The MX missile design is not best suited for airborne carriage. In point of fact, the specially developed airplane which is being proposed may not be necessary. It is an open question whether one should design the carrier aircraft for one large missile with ten warheads or for two or three Minuteman III's with three warheads each, or perhaps for several small missiles each carrying a single warhead.

The number of trained crews is significantly larger than the number of airplanes in the air all the time. Six-day continuous airborne missions are beyond the experience to date.

3. The continuous airborne alert basing has a number of undesirable side effects

The number of peacetime takeoffs and landings with the associated risk of crashes involving live nuclear weapons raises the question of environmental impact due to plutonium contamination. The problem could be partially solved by redesigning and procuring oralloy based warheads, but such designs and weapons are not now available in stockpile.

Attacks against the main operating bases or against the emergency recovery bases, aimed at destroying the endurance of the airborne deployment could result in several tens, and possibly hundred, million casualties.

4. A number of technical, schedule, and cost risks are associated with the continuous airborne alert basing

Nuclear hardening of MX-carrier aircraft.

Ejection of missile from aircraft, postlaunch stresses and flight dynamics.

New navigation/ guidance initialization system.

New, dedicated special-purpose missile carrier aircraft.

Design of all-oralloy nuclear warheads.

All these put an early IOC date at considerable risk.

The Seattle Times (Jan 14, 1990) - `The Fall Guy' Speaks Out -- But Convicted Ex-Boeing Official Refuses To Name Sources

[HN01C1][GDrive]

By Duff Wilson / COPYRIGHT, 1990, Seattle Times Company

CUTLINE: DON PREISLER: ON THE WALLS OF HIS HOME IN SPRINGFIELD, VA., RICHARD FOWLER KEEPS NUMEROUS MEMENTOS FROM HIS DAYS OF DEALING WITH PENTAGON OFFICIALS AS MARKETING ANALYST FOR THE BOEING CO., AMONG THEM THIS PLAQUE SIGNED BY FRIENDS IN THE PENTAGON.

A few days before he was sentenced to prison for his part in what prosecutors called a black market in classified Pentagon budget documents, former Boeing official Richard Fowler spoke on the record for the first time about his work, his case and the reasons he chose to go to jail rather than reveal his sources. He talked for more than 20 hours with Seattle Times reporter Duff Wilson, on condition his remarks not be published before his sentencing last Friday.

SPRINGFIELD, Va. - In a rented brick townhouse on a quiet street here last week, **Richard L. Fowler**'s friends and relatives phoned to wonder why he didn't just tell authorities what they wanted to know.

Had he talked, he might not be in jail today.

For more than four years, federal investigators had zeroed in on the man they would call the defense industry's mother lode of classified Pentagon documents. It ended with the shutting of a cell door Wednesday morning, when Fowler went to jail for refusing to say who gave him the secret budget documents. On Friday, he received a two-year prison sentence for passing them on to The Boeing Co. and other major defense contractors.

All along, Fowler has insisted it was the job that a Boeing vice president had specifically hired him to do.

He thought it was legal. He said everybody was doing it. It was ``as common as trading baseball cards.''

Now Fowler, 64, describes himself as ``the fall guy'' in a government ``witch hunt'' to plug the Pentagon leaks. But he refuses to name the sources, despite the pleas of lawyers and family members.

``Yeah, I know I make you mad,'' Fowler told a friend on the telephone a few days before he went to jail. ``I've made a lot of people angry, and a lot of people don't understand, and I'm not asking that people understand. But if I talked, I wouldn't be able to face myself in the mirror.''

Fowler, a senior marketing analyst for Boeing between 1978 and 1986, is the first person to be convicted in what prosecutors said was a far-reaching conspiracy among employees at Boeing and other defense contractors with whom he shared and traded the documents.

On Dec. 7 Fowler was convicted of one count of conspiracy to defraud the government, 18 counts of conveying government documents without authority, five counts of converting the documents to his use and 15 counts of mail fraud for having them sent to Boeing.

But his own view is that the investigation and prosecution of him boiled down to a test of ``my integrity, trustworthiness and loyalty.''

In one of a stack of ``position papers'' he has painstakingly hand-written over these past many months, Fowler says, ``I am here today not for what I did; I'm here for what I did not do'' - name his sources. Fowler says he was offered immunity in March 1987 if he would cooperate. The chief investigator on the case said his office checked with prosecutors and they could not recall any such offer. But no one disputes that Fowler's sources are the ultimate goal of the continuing federal probe.

``Good, patriotic, honest government employees who had no idea what they were doing was wrong,'' Fowler calls them, his voice rising with emotion.

He shuffles through his piles of notes to remind himself of all that has happened. He has lost weight and developed a skin condition from nerves, he says.

Though his lawyer advised him against giving any interviews, he is talking, he says, because he feels the public might understand what the justice system did not.

The Pentagon classifies its spending projections for weapons systems largely to keep them out of the hands of meddlesome members of Congress before they are finalized and presented by the president, according to Fowler and two other former Pentagon workers who knew him. They said the plans were often informally released to companies in the defense-contracting business so they could do a better job of using research money and preparing to compete for contracts.

Fowler's job was to obtain Pentagon financial and budgetary information for Boeing. From years of work inside the Pentagon, he had the best Air Force sources. He swapped ``secret'' documents with industry representatives who had better sources in the Army, Navy and Office of the Secretary of Defense. Fowler, who had government clearance to handle ``secret'' documents legally given to him, entered the documents in a Boeing log book and assumed the practice was legal because Pentagon inspectors checked the log every six months.

Boeing officials have admitted that the company acquired and used the documents, but stopped five years ago. Boeing spokesman Paul Binder says the company will have no other comment on the Fowler case. And Fowler has taken on the singular responsibility of protecting the sources who made him a success at Boeing.

His sources' jobs, their pensions, perhaps even their freedom, are at stake, Fowler says. He knows the experience of personal ruin.

After 25 years of government work and eight years at Boeing, Fowler is nearly broke. He and Muriel, his wife of 35 years, owe back taxes. They rent their

After 35 years of government work and eight years at Boeing, Fowler is nearly broke. He and Muriel, his wife of 35 years, owe back taxes. They rent their house, lease their cars. They are getting by on Muriel's job with a real-estate office and his $231-a-month Boeing pension. Their federal pension went down the drain with the felony conviction.

``There isn't a soul out there who can put themselves in our shoes,'' says Muriel Fowler, 62. ``And I'm not talking hardened criminals - I'm talking patriotic, law-abiding citizens. Right now I am very bitter, and I'm not through fighting yet. That's all I'm going to say.''``Of course my family has some reservations,'' Richard Fowler says of his decision to protect his Pentagon sources. ``They'd have to. Like my daughter, at the beginning, the very beginning, said `Dad, I'd rather have a snitch for a father than a jailbird.' And then she's turned completely around, and now she's saying `My father's a hero.' ''

``I have to admire him,'' Muriel Fowler admits. ``But I don't always understand it.''

Fowler said the sources didn't need to ask him to assure their anonymity when he was getting several hundred classified budget documents over the years. They didn't imagine they were doing anything criminal. And the sources haven't needed to beg him - or even thank him - for keeping the secret since.

In fact, Fowler said, he hasn't heard a word from any of his old sources in nearly two years.

``I don't care what they expect or don't expect,'' Fowler says with the kind of resignation acquired from years of preparing to go to prison. ``I'm doing this out of my own - what do I say? compassion? - my own self-respect.''

He thinks his sources are ``smart enough to just stay away and have no contact. I mean, these are not people who are inconsiderate, but they know enough to keep a respectful distance.''

Boeing has kept its distance, too. Nobody from Boeing telephoned Fowler for a year and a half until last week. Then three employees called to wish him well. One said he had gotten his supervisor's permission to phone

``Well, I can understand why I haven't gotten a lot of calls from people,'' Fowler said. ``They don't know what to say. All I can say is, hell, I can take it, because I can hold my head up high.''

Why is Fowler so steadfastly protecting his sources?

``We wonder about it all the time,'' an in-law said.

The price Fowler is paying also causes people to wonder if he has hidden motives.

Is he being paid off? Investigators have never suggested that Fowler, his sources or Boeing was involved in payoffs or bribery of any form. The only money involved was Fowler's salary, which rose from $29,500 to $56,200 during eight his years with Boeing.

So, is he protecting some military brass or Boeing executive? Again, nobody connected to the case has alleged that. Fowler was a middle-level worker with a high-school education. He said he kept his nose to his work and stayed out of company politics. Fowler's concerns are with smaller, more personal things, like his old friends' pensions.

Is it possible he is making the sources up? Did he sneak into the Pentagon and steal the documents to impress Boeing? ``Absolutely not,'' says the chief of the investigation, Michael Costello of the Defense Criminal Investigative Service, a Pentagon watchdog.

There is simply no explanation to rival the one that Fowler gives - that he got the documents from old friends, whom he will not betray.

``If you're in trouble, why pull somebody else in with you?'' Fowler asks.

Costello wants the leakers punished to send a message to other people who might give away classified documents.

``They were put in a position of trust, and they violated that,'' Costello said in a recent interview. ``They independently and capriciously made decisions to give this information to an individual who was not entitled to it by any stretch. There are a lot of reasons these people should be slam-dunked.''

But so far, Fowler is the only one convicted in the case. And so far, he's taken his punishment with equanimity. He stood erect before the jurors who found him guilty, and looked them calmly in the eye.

For now, Fowler is willing to go to jail for his Pentagon sources, though he sees a point when he might name them. In nine months, it will have been five years since he received his last classified document from one of them. The statute of limitations on criminal charges will expire.

Costello agreed that the statute of limitations was ``the controlling factor'' in the investigation of the leaks. He said the government has a good idea who the sources are, but not enough to prosecute.

``We need a little bit to put this thing over the edge, and Fowler could be that,'' he said. ``We'll see how long he can sit in jail.''

The case has national importance. With or without his sources, Fowler set the precedent in what Costello says will be similar prosecutions this year of ``a lot of people and a lot of companies'' that were involved in unauthorized use of Pentagon budget documents.

Fowler says he has handled classified documents since he was a 16-year-old messenger for the War Department. His father was a civil engineer who helped build one side of the Pentagon. During World War II as a gunner, the younger Fowler suffered a broken neck when a B-29 went down in the ocean during a training exercise.

Fowler missed action because of the accident, but he did report to the Philippines and flew over Hiroshima and Nagasaki four days after the atomic bombs hit.

Fowler went to work as a civilian in the Pentagon the next year. He progressed through the ranks until he reached a job in the Air Force Research and Development office.

``The job was challenging. I had established myself. I had a good name.''

And there he stayed for 18 years. As a budget officer for missile programs, Fowler had frequent contact with Boeing and other contractors. He received the Award for Meritorious Civilian Service, the Pentagon's top award for a civilian.

At home, Fowler took pride in his principles. He picketed a local car dealer for two days when the dealer wouldn't fix a problem on his teen-age son's new car.

Fowler quit the Pentagon in 1978. He said President Jimmy Carter's zero-based budgeting was a paperwork nightmare. Shortly after that, Boeing offered him a job. Fowler said he was hired by Ben Plymale, then vice president for marketing. (Plymale died in 1981.)

Fowler says Boeing had scores of marketing analysts who were all trying to get inside information, including budget projections, at the Pentagon. Fowler's job was to get those budget documents, freeing up his fellow analysts for other areas.

Fowler says Plymale told him his sources were nobody's business, and Boeing's security chief told him it was legal as long as he entered the documents into Boeing's classified-documents security system.

Financial intelligence-gathering was nothing new at Boeing. When Fowler joined Boeing in 1978, a woman named Gloria Mahaffey was operating a secret library in the company's office in Kent. Boeing kept its cache of classified Pentagon budget documents there for review by select marketing officials, Mahaffey said at Fowler's trial.

In 1979, for reasons that are unclear, Boeing began handling the classified documents with tighter security. They were all logged into the company's classified documents accountability system in Rosslyn, Va. Inspectors for the Defense Investigative Service checked the log twice a year, and they didn't raise questions until 1986.

Fowler said the log was one reason his Pentagon sources trusted him so much. They knew Boeing was handling the documents carefully. He said it was also a reason the government targeted Boeing. They had a road map to the evidence.

The worst mistake Fowler will admit to is putting some of the classified information in his weekly activity reports. Those were not classified. In some cases, his superior repeated the information in his own report, which was circulated to 268 Boeing employees.

Fowler says Boeing wanted the documents for many reasons. The company could direct its research money to areas the Pentagon was planning to finance. It could look for opportunities to compete.

Fowler was named one of Boeing's Marketing Employees of the Quarter in June 1986. Everything was going along fine - fine, that is, until the Pentagon's Defense Investigative Service started raising questions.

Behind the scenes in the early 1980s, Defense Department investigators and the Department of Justice had been trying to decide whether to crack down on the bootlegging. It was part of a broader move to plug leaks.

One former head of the Defense Procurement Fraud Unit of the Justice Department argued that the cases were not conspiracies. A Defense Department inspector general appealed to higher-ups to pressure the Justice Department to bring a case.

In October 1985, Bernie Zettl, a consultant for the Connecticut-based GTE Corp., was indicted.

Fowler says Boeing speeded up its usual schedule of destroying out-of-date documents after he heard a warning that contractors should get rid of their classified Pentagon documents.

Push came to shove over Fowler's sources in 1986. The Defense Investigative Service challenged Boeing's possession of 59 classified budget documents.

Fowler told a company investigator that he had obtained the reports from five friends in the Air Force Research and Development office. He says he was conned into identifying one of them, who had retired, on the promise that investigators would be satisfied the leak was plugged.

But that was not enough, he says. And after he saw the ``devastated look'' on that source's face when he told him the news, Fowler resolved never to reveal another source.

Boeing fired Fowler in September 1986. He says he is not bitter.

``They had no choice but to fire me,'' Fowler explains. ``I violated the industrial security manual by not cooperating with the investigation. Boeing was facing suspension from government contracts if they didn't do something.''

Boeing, he says, is the best company he ever worked for.

Muriel Fowler scoffs at the idea. ``You got screwed, and you didn't even get a kiss!''

Fowler, sipping a mai tai, shrugs. ``I can't do nothin' about it.''

Last year, Fowler says, the government twice offered him plea bargains on crimes with a maximum penalty of 15 years in prison if he gave up his sources. He says he rejected those offers, too.

Fowler's stubbornness grew as his trial approached last month. He was hoping to get off. He lost the gamble.

Six officials with other companies and 10 current and former Boeing workers were granted immunity as part of the Fowler prosecution. Former Defense Secretary Frank Carlucci and a number of generals testified that the classified reports should never have been released; Fowler responds that they were out of touch with the reality at the working level.

The jury deliberated just two hours. One juror later said many of the jurors had believed Fowler was a scapegoat but had no choice but to convict him.

Fowler's insistence on protecting sources had influenced the trial strategy. He says one of the main reasons he did not testify on his own behalf was that he believed he would have been asked once again to name his sources. When he refused, he could have been held in contempt of court. That would have meant going to jail and missing Christmas at home with his family.

Last Monday, Fowler's lawyer sent him one more appeal to name the sources. The lawyer, Cary Feldman, wrote Fowler that investigators already had a good idea who the sources were. He argued that Fowler's cooperation with a grand jury probe would not hurt the sources much, if he didn't tie them to specific documents.

Refusal, Feldman warned, would mean certain jail time and possibly a longer prison sentence.

Fowler didn't budge. On Tuesday, he says, he told the federal grand jury he could only reveal the sources for documents named in 162 of the 334 ``overt acts'' cited in his indictment. Those sources were dead or had been granted immunity. They were employees of Boeing or other contractors.

Fowler says he feels free to speak about Boeing because the company obtained immunity for its employees' acts as part of a corporate plea agreement last

November.

Boeing itself, unscathed by other recent contracting scandals, admitted guilt to one felony for receiving classified budget reports and agreed in a negotiated plea bargain to pay $5.2 million restitution and fines.

Boeing made nearly $3 million per working day in profits last year.

``The Boeing Company's fine, in exchange for total immunity, was a bargain, but appears to have sacrificed a single participant,'' retired Air Force Lt. Col. Richard C. Coupland Jr. wrote in a letter to U.S. District Judge Albert Bryan Jr. before Fowler's sentencing.

Boeing's field office in Rosslyn is applying for reinstatement from a suspension action that has prevented its estimated 100 employees from having contact with government contract officers.''

Meanwhile, Boeing's work can be done from its other offices - ``as if nothing had happened,'' says Charles H. Welling Jr., manager of Boeing Aerospace Company's field marketing offices from 1974 to 1979, who also wrote the judge on Fowler's behalf.

``Although Dick broke the law, he never derived any personal gain from his actions but was always motivated by a desire to benefit the company,'' wrote Welling, who had helped hire Fowler.

At a Christmas party last month, a group of Pentagon and industry people were talking about the Fowler case and agreed they had let him down, according to one industry consultant who used to work with Fowler at the Pentagon.

``Everybody in the industry is scared,'' he said. ``What could we do? Speak up for Dick? If we did, we'd probably be targeted.''

Anthony Asterita of Mount Vernon, Va., worked with Fowler in the Pentagon between 1974 and 1978, then retired at the rank of lieutenant colonel and went to work in the industry. He said the ``secret'' budget information actually had little value and was widely shared through the early 1980s.

``The value to a contractor like Boeing is to structure long-range planning,'' Asterita said. ``And who benefits from it? The military benefits from it, because you have a more informed industrial base.''

Asterita said he had to admire what Fowler has done in protecting his sources from harm.

``The guy has made a lot of thought about it, I'm sure,'' he said. ``He is sacrificing family life at his age, which is children and grandchildren, in order to stick to what he believes.''

1983 (March 16) - NY Times - "BIG SEVERANCE PAYMENTS BY BOEING TO 3 PENTAGON AIDES UNDER INQUIRY"

[HN01C2][GDrive]

By Jeff Gerth, (March 16, 1983)

A Federal grand jury is investigating the cases of three Boeing Company executives who received at total of $400,000 in severance payments when they left the company in 1981 to take high-level Defense Department positions in the Reagan Administration, according to officials in the Government and the company.

The investigation, which began last summer, according to law enforcement officials, is to determine whether the severance payments were larger than or different from those normally paid by Boeing to executives who resign, whether they constituted a conflict of interest and whether the officials reported the payments properly on the public financial statements Government officials must file.

It is against the law for companies to pay extra compensation to employees who enter the Government. The officials under investigation are [Melvyn Robert Paisley (born 1924)], Assistant Secretary of the Navy for research, systems and engineering; T.K. Jones, Deputy Under Secretary of Defense for strategic theater nuclear forces, and Herbert A. Reynolds, Deputy Director of the Defense Department's Office of Intelligence and Space Policy.

Mr. Jones and Mr. Paisley declined numerous requests for interviews and did not respond to written inquiries left with them last week. But, according to Government officials, they denied any wrongdoing when questioned by Federal investigators.

Mr. Reynolds said that whatever he received from Boeing was "perfectly proper." "I haven't done anything wrong," Mr. Reynolds said. "Boeing is not going to gain from what I do. If I have any residual loyalty it's to the Government, where I served 27 years, not to a company where I spent five years." Mr. Reynolds was for 27 years an Air Force officer before retiring as a lieutenant colonel and going to work for Boeing.

The Defense Department declined to comment on the investigation. Boeing, in a statement, said that it was fully cooperating with the Government's requests for information and that the company "has done nothing unlawful, unethical or otherwise improper."

The so-called revolving door between the Defense Department and military contractors has often been studied, but, according to authorities in the area, this may be the first time that a criminal investigation has focused on payments to aerospace executives entering the Pentagon.

Boeing was the nation's sixth largest defense contractor last year, receiving $3.2 billion in fiscal year 1982, up from $2.6 billion in 1981 and $2.3 billion in 1980, Defense Department figures show. Last year, the head of Boeing's aerospace divisions predicted that further gains could be expected over the next few years, in part because of more than a billion dollars in expected new contracts with the Navy.

The Secretary of the Navy, John F. Lehman Jr., who was a consultant to Boeing before taking office in 1981, is also under investigation by the Justice Department, according to Government officials. Mr. Lehman has denied any wrongdoing.

Consulting Company Involved

The Lehman inquiry is separate from the Boeing investigation. It involves the Abington Corporation, a defense-related consulting company owned by Mr. Lehman, the officials said. Before 1981, Abington earned $350,000 a year from Boeing, and Mr. Paisley was the main point of contact between Boeing and Abington, according to a former Abington employee. The issue in the Lehman investigation, according to authorities, is Mr. Lehman's handling of his interest in Abington after he entered the Government.

After taking office in 1981, Mr. Lehman retained his ownership of Abington and, for $60,000, gave the use of Abington's name abroad temporarily to Lord Chalfont of Britain. Lord Chalfont said he had retained some of Abington's clients, including Boeing.

Boeing declined to disclose the size of the severance payments and other compensation to Mr. Paisley, Mr. Jones and Mr. Reynolds or to say how they compared with those of other employees of comparable rank. Government officials said the payments to the three men totaled $400,000, but the officials did not provide a breakdown. Public records and other documents show these figures:

Mr. Paisley earned a total of $180,000 in salary from Boeing in 1980 and the first part of 1981, according to a financial disclosure statement dated June 1981, three months before he left the company. The statement also showed holdings of $100,001 to $250,000 in Boeing's Voluntary Investment Plan. Mr. Paisley and Boeing had contributed to this.

Records from a 1980 divorce case show much lower income in previous years and an investment plan value of only $68,000 as of September 1979. The supervisor of Boeing trust funds' accounting department said she was puzzled how the value of Mr. Paisley's investment program holdings could rise so much in 21 months.

Mr. Jones, in a June 1981, financial disclosure statement, listed a 1980 salary from Boeing of $68,200. For 1981, he originally showed income of $176,900, but that figure was crossed out and changed to $200,300, which included "income from company sponsored investment plans."

Mr. Reynolds's disclosure statement, dated July 1981, listed no income or payments from Boeing, where he was employed from 1976 until Aug. 1, 1981. Mr. Reynolds said that his income from Boeing was a private matter and that Defense Department officials had told him he was not required to disclose his Boeing salary.

David R. Scott, acting head of the Office of Government Ethics, said that incoming Government officials like Mr. Reynolds were required under the law to disclose any income they received in the previous two years. Mr. Reynolds said he would disclose his compensation if asked by the Defense Department. A Defense Department lawyer said today that Mr. Reynolds was asked to amend his original disclosure statement after investigators learned of his severance payment. The lawyer said that the Justice Department took jurisdiction of the case away from the Pentagon before Mr. Reynolds fully complied with the request.

No Direct Involvement Seen

After the investigation began, the three men, at the request of the Defense Department, disqualified themselves from dealing with matters involving Boeing, according to a Pentagon lawyer. The lawyer said that he did not know whether they had dealt with Boeing before they disqualified themselves.

From 1970 to 1979, 388 officials moved back and forth between Boeing and the Pentagon, the largest for any military contractor, according to a 1981 study by the Council on Economic Priorities, a nonprofit research group.

There are many ties between Boeing and the Reagan Administration. They date from the transition period, when the deputy head of the Reagan transition team for the Defense Department was a Boeing vice president, Benjamin T. Plymale. Mr. Reynolds said he served with Mr. Plymale on the transition team. Mr. Plymale, who died in August 1981, supported the choice of Mr. Lehman and Mr. Paisley for their Government positions, according to Administration sources and former Boeing employees.

Mr. Plymale also helped introduce Mr. Lehman and Mr. Paisley, according to former associates. Other Administration officials with ties to Boeing include Richard N. Perle, Assistant Secretary of Defense for international security policy, who worked for Mr. Lehman's Abington Corporation and did consulting work for Boeing, according to public documents, and Ronald M. Mann, who left Boeing for the White House, where he is associate director for Presidential personnel in the national security area.

One Finds Severance Small

Neither Mr. Perle nor Mr. Mann is under investigation. Mr. Mann said that Boeing's 1981 severance payments to him, $13,000 according to Mr. Mann's financial disclosure statement, were less than generous. Mr. Mann, whose salary at Boeing for 1980 and part of 1981 was $65,000, said he did not participate in Boeing's voluntary investment plan.

The investigation of Boeing's severance payments was referred to the Justice Department from the Defense Department after the Defense Contract Audit Agency came across the payments, according to Government officials. The audit agency examines the books of military contractors and evaulates the acceptability of costs claimed or proposed.

According to Government officials, the three Defense Department officials denied any wrongdoing in interviews with the Federal Bureau of Investigation, which is assisting in the investigation. The bureau also interviewed Boeing officials, the officials said.

One Federal law on conflict of interest at issue in the investigation is Title 18 Section 209, which makes it a crime for the salary of Government officials to be supplemented by non-Government sources.

Lawyers for Boeing said they could not find record of any criminal prosecutions under this staute in the last 65 years. The statute became an issue last year when, after news accounts of the matter, Attorney General William French Smith returned a $50,000 severance payment he had received from a company upon entering the Government.

Norms for Severance Involved

According to Government lawyers, a key factor in any prosecution under Section 209 would be whether the severance payments to an person who resigned to enter the Government differed from severance payments to other employees.

Boeing has several programs under which employees receive compensation upon leaving. The basic terms are detailed in the company's proxy statement.

In a statement, Boeing says it had "as is commonplace in industry, paid severance compensation to employees who left the company to enter Government

In a statement, Boeing says it had, "as is commonplace in industry, paid severance compensation to employees who left the company to enter Government service." The statement did not address the question of how payments to Mr. Paisley, Mr. Reynolds and Mr. Jones compared with compensation paid other employees who left Boeing.

Details about some of Mr. Paisley's compensation from Boeing came out in the divorce trial in Seattle in 1980. According to court records of the proceeding between Mr. Paisley and Mildred, his third wife, and his income tax returns, his average income from 1974 and 1979 was $60,000 a year. By contrast, for 1980 and part of 1981, Mr. Paisley earned a total of $180,000 from Boeing, according to his financial disclosure statement.

Value of Investments at Issue

In October 1979, in response to a subpoena, Boeing told Mrs. Paisley's lawyer that as of Sept. 1, 1979, Mr. Paisley's Voluntary Investment Plan was valued at $68,000. In the June 1981 financial statement, Mr. Paisley placed his holdings in the $100,001-to$250,000 bracket.

Portsmouth Gaseous Diffusion Plant

Wikipedia Portsmouth Gaseous Diffusion Plant

Saved Wikipedia (Sep 28, 2020) : Portsmouth Gaseous Diffusion Plant

[HK005A][GDrive]

The **Portsmouth Gaseous Diffusion Plant** is a facility located in Scioto Township, Pike County, Ohio, just south of Piketon, Ohio that previously produced enriched uranium, including weapons-grade uranium, for the United States Atomic Energy program and U.S. nuclear weapons program. The plant is in shutdown status and is in preparation for decontamination and decommissioning (D&D), with some facilities overseen by the United States Enrichment Corporation, a subsidiary of USEC Incorporated, a publicly traded corporation (NYSE: USU). The D&D work on the older facilities to prepare the site for future use is expected to continue through 2024 and is being conducted by Fluor-B&W Portsmouth LLC.

The Portsmouth plant, so named because of its proximity to the city of Portsmouth, Ohio, was one of three gaseous diffusion plants in the United States, alongside the K-25 plant in Oak Ridge, Tennessee and the Paducah Gaseous Diffusion Plant in Kentucky. The plant was constructed from 1952–1956, with the first enrichment cells going online in 1954. The plant was operated by the Goodyear Tire and Rubber Company from its startup to 1986, when the contract was taken over by Martin Marietta. In 1993, the USEC took overall responsibility for the Paducah and Portsmouth enrichment plants, continuing the operating contract with Martin Marietta. In 1995, the operator became Lockheed Martin with the merger of Martin Marietta and Lockheed. In May 2001, the Piketon plant ceased operations and was placed in cold standby. In 2006, the site work shifted into cold shutdown transition in preparation for future Decontamination and Decommissioning (D&D).

The former gaseous diffusion plant covers 640 acres (260 ha) of the 3,777-acre (1,528 ha) site. The largest buildings, the process buildings, have a combined length of approximately one and a half miles (2.4 km), and cover about 93 acres (38 ha) and contain 10 million square feet (0.93 km^2) of space. In use, the plant consumed a peak electrical demand of 2,100 megawatts.[1]

A commercial centrifuge plant at the Portsmouth site began construction in May 2007 for the production of commercial nuclear fuel for power reactors. Once completed, the commercial plant will use approximately 11,500 centrifuge machines to generate 3.8 million separative work units(SWU) a year.[2]

History – The Portsmouth Project[edit]

In August 1952, the U.S. Atomic Energy Commission (AEC) selected Scioto Township, a rural area occupied by family-owned farms, as the site for a new gaseous diffusion plant to produce highly enriched uranium, U-235, for use in military reactors and nuclear weapons production. Located near the junction of

the Scioto and Ohio rivers, the site was chosen due to the economic availability of electric energy, availability of water for plant operation, adequate potential labor, suitable transportation facilities, geographic traits, and relative flatness of the topography.[3]

The project was given expedited priority. **Due to this prioritization, construction of the site had to start before all the architectural drawings for the site were completed. The Oak Ridge operations of the AEC set up an organization designated "The Portsmouth Area" to direct construction and operation of the plant, select engineers, construction contractors, schedule delivery of critical materials, and any other contingency.** Uniform agreements were set up between labor and management to minimize the number of stoppages. Early planning and organization took place in improvised offices in city buildings of Portsmouth, including the National Guard Armory, the Elks City Club, and the old farmhouses on the site itself. Nine architect engineer firms shared in the design of the plant, producing 12,000 design drawings, 40,000 construction drawings, and 16,000 shop drawings. Advanced planning and scheduling were extremely important because the plant was designed to go into operation, or "on stream," as soon as each unit or segment in a process building was completed while construction continued in other parts of the building.

Groundbreaking for the plant was November 18, 1952. Earthmovers began leveling the rolling farmland for the building foundations on the same day. One hundred thousand short tons (91,000 t) of structural steel, 14,500 short tons (13,200 t) of reinforcing steel in the concrete floors, 600 miles (970 km) of process piping and 1,000 miles (1,600 km) of copper tubing were used in the construction of the three process buildings. An additional 1,000 miles (1,600 km) of tubing ran through the rest of the plant and into the control rooms. Five hundred thousand cubic yards (380,000 m^3) of concrete were required to complete the project. To support this, a separate concrete batching plant was constructed on plant site to serve all contractors. It produced 200 cubic yards (150 m^3) of concrete per hour. It took 70 million man hours for construction.

Two railroad lines, financing their own work, built spurs into the area to haul in building materials and heavy equipment including 22 miles (35 km) of track on site. Twenty-five miles (40 km) of roads were laid in the plant area as well as a seven-mile (11 km) perimeter road that encircles the plant.

The original estimate for construction was four years at a cost of $1.2 billion. Construction was carried out by Peter Kiewit and Sons of Nebraska at a cost of $750 million. The site was completed several months ahead of schedule at 34 percent below the original cost estimate at a $400 million savings.

Operation[edit]

Operations began in 1954 while construction was ongoing with the plant coming fully online in early 1956, several months ahead of schedule.

The primary mode of enrichment was the gaseous diffusion of uranium hexafluoride to separate the lighter fissile isotope, U-235, from the heavier non-fissile isotope, U-238. The plant initially produced material for the U.S. nuclear weapons program. In the mid-1960s, the plant converted to fuel production for commercial nuclear power plants. Portsmouth took material from Paducah that was enriched to 2.75% U-235 and further enriched it to approximately 4% and 5%.[4][5]

The Portsmouth plant had a capacity of 8.3 million separative work units per year (SWU/year) in 1984 in 4,080 stages. Three buildings, X-326, X-330 and X-333, housed gaseous diffusion equipment.[6] Three cooling tower complexes, X-626, X-630, and X-633, were used to remove process heat. Six hundred eighty-nine million US gal (2,610 million l) of water went through the 11 cooling towers daily, of which 20 million US gal (0.076 billion l) evaporated into the air. Water came from well fields installed at the Scioto River supplying 40 million gallons per day when operating at full capacity.

To support operations, the AEC entered into the largest contract for a single customer in the history of the electrical utility industry for power at that time. Power usage was equal to the all-time high voltage requirements in the United States, more than 2,000 megawatts - 18 billion kilowatt hours yearly. To handle the power requirements, two large switchyards were constructed on site. Two large steam electric generating stations were built to supply power at Clifty Creek in Madison, Indiana and Kyger Creek in Gallipolis, Ohio. At the time, they were the largest power plants built by private industry as well as the most efficient, producing 1 kilowatt hour of electricity for 0.7 pounds (0.32 kg) of coal. The power plants used 7.5 million short tons (6.8 million t) of coal annually to support operations.

In May 2001, USEC ceased uranium enrichment operations at the Piketon plant and consolidated operations in Paducah. The following year, transfer and shipping operations were also consolidated in Paducah.[2][3] Although USEC had nine years time and had received the funding, USEC ceased the Portsmouth enrichment cascade in a dirty power down, without purging the diffusion cells.[7] Geoffrey Sea wrote in September 2013 that USEC's demise will be either by creditors (by October 2014 loan repayment deadline), "regulators who find their spines", or by "repeal of the USEC Privatization Act by Congress."[8]

DUF6[edit]

DUF6 Conversion facilities are located at the Paducah Gaseous Diffusion Plant near Paducah, KY and the Portsmouth Gaseous Diffusion Plant near Piketon, OH. Each facility consists of four buildings- a conversion building, an administration building, a warehouse and a KOH Regeneration building, as well as rail heads, five large acid storage tanks and lay-down areas for DUF6 steel cylinders. In 2002, DOE awarded Uranium Disposition Services, LLC (UDS) a contract to design, build and operate the DUF6 conversion plants to convert the DUF6 to uranium oxide and hydrofluoric acid. In December 2010, DOE awarded B&W Conversion Services, LLC (BWCS) a contract to operate the DUF6 Conversion Plants through March 2016. Babcock & Wilcox Conversion Services (BWCS) completed the transition of the contract for initial operations of the DUF6 Project in March 2011. Both plants are expected to be fully operational in fall 2011.[9][10]

Centrifuge separation[edit]

USEC ceased enrichment operations at the Portsmouth Gaseous Diffusion Plant in May 2001 after it consolidated operations at the Paducah Gaseous Diffusion Plant in Kentucky. USEC began working with the U.S. Department of Energy (DOE) in 2000 to resume gas centrifuge enrichment operation activities, which DOE originally began developing in the early 1960s. During the 1980s, DOE had begun construction of a centrifuge enrichment plant at the Portsmouth site before abandoning the project in June 1985 after spending $3 billion. USEC sited its Lead Cascade Test Program at Piketon in late 2002. The Nuclear Regulatory Commission (NRC) licensed this demonstration facility in 2004. Lead Cascade operations using prototype machines commenced in August 2007.

In March 2010, USEC began operating a new test cascade of commercial-ready AC100 centrifuge machines. USEC has been demonstrating AC100 cascade operations since then. USEC's prototype and AC100 centrifuge machines have accumulated hundreds of thousands of hour of runtime since August 2007. Performance of the Lead Cascade has been confirmed under a variety of operating conditions with product assays consistent with industry standards for the

production of commercial nuclear fuel for power reactors. The NRC licensed USEC to construct and operate the commercial American Centrifuge Plant at the Portsmouth site in April 2007, and construction began in May 2007. Construction was demobilized in August 2009 due to the delay in receiving a loan guarantee from the U.S. Department of Energy. USEC currently awaits approval of this $2 billion loan guarantee before it can remobilize the construction, which will create nearly 8,000 jobs in the United States. Once completed, the commercial plant will use approximately 11,500 centrifuge machines to generate 3.8 million separative work units (SWU) a year.[2]

Decontamination and ongoing cleanup[edit]

During its nearly 60 years of operations, the cleaning, maintenance, and change out of process equipment at the site generated spent solvents and other contaminants that were disposed of in onsite landfills and surface storage buildings. To date, contamination has been found in various locations on site including the process buildings, the former cooling towers, landfills, waste water ponds, and other buildings. There are also groundwater plumes from the landfills. The Ohio EPA is monitoring cleanup operations, pursuant to a 1989 consent decree.[11]

On June 27, 2005, the Department of Energy awarded a contract to LATA/Parallax Portsmouth, LLC (LPP). This was the first small business contract by DOE at the Portsmouth site. As part of the environmental remediation of the site, LPP removed 31 facilities; an 18-acre switchyard complex which included 160 towers, 18 large transformers, 10 synchronous condensers, 2 switch houses, 1 2-story control room and numerous other structures. LPP's contract was extended as part of the American Recovery and Reinvestment Act of 2009 (ARRA) stimulus project with their contract ending on March 29, 2011.

In 2008, a large project was completed to remove 7,640 short tons (6,930 t) of scrap material by shearing and disposing of 382 old process equipment converter shells. Between 2003 and 2010, more than 2.10 million cubic feet (59,500 m^3) of legacy waste was removed from the site.

In September 2010, the DOE awarded the $1.2 billion follow up contract to Fluor-B&W Portsmouth LLC. Fluor-B&W transitioned the remaining LPP scope and workforce on March 29, 2010 and is currently working with USEC to transition remaining personnel and responsibilities for the site.

Nuclear power[edit]

The site was evaluated for a potential nuclear power plant by a consortium including Areva, Duke Energy, USEC and UniStar Nuclear Energy, with no proposal as of 2011.[12]

The future of the site[edit]

The DOE, in partnership with the counties of Pike, Jackson, Ross, and Scioto and the D&D contractor, Fluor-B&W Portsmouth, are working on preparing the site for future use.

Site reopening[edit]

On January 7, 2019, US Senator from Ohio Rob Portman announced that the Trump Administration has earmarked $115 million to open the facility again, employing 60 people which would house a cascade of 16 centrifuges for uranium enrichment, subject to EPA final approval.[13]

May 2019 Event[edit]

On May 13, 2019, enriched uranium was detected inside the Zahn's Corner Middle School, in Piketon, Ohio, just two miles (3.2 km) from the plant. The U.S. Department of Energy air monitor adjacent to the middle school also detected neptunium 237 -- a byproduct of nuclear reactors and plutonium production. It was determined by leaders to close the school for the rest of the school year. Area businesses, homes, ground and groundwater were also undergoing further testing. [14] This event has resulted in a Class Action Lawsuit filed on behalf of area residents by a group of attorneys led by toxic tort specialist Stuart Smith.[15]

Scientific career

Fields Computer science

Doctoral advisor Dave Farber

Influenced Tim Berners-Lee[1]

Jonathan Bruce Postel (/pɑːl stɛl/; August 6, 1943 – October 16, 1998) was an American computer scientist who made many significant contributions to the development of the Internet, particularly with respect to standards. He is known principally for being the Editor of the Request for Comment (RFC) document series, for Simple Mail Transfer Protocol (SMTP), and for administering the Internet Assigned Numbers Authority (IANA) until his death. In his lifetime he was known as the "god[2] of the Internet" for his comprehensive influence on the medium, although Postel himself noted that this "compliment" came with a barb — with the article that introduced it also suggesting that he should be replaced by a "Professional."

The Internet Society's Postel Award is named in his honor, as is the Postel Center at Information Sciences Institute, University of Southern California. His obituary was written by Vint Cerf and published as RFC 2468 in remembrance of Postel and his work. In 2012, Postel was inducted into the Internet Hall of Fame by the Internet Society.[3] The Channel Islands' Domain Registry building was named after him in early 2016.[4][5]

Career

Postel attended Van Nuys High School,[6] and then UCLA where he earned his B.S. (1966) as well as his M.S. (1968) in Engineering. He then went on to complete his Ph.D. there in Computer Science in 1974, with Dave Farber as his thesis advisor.

Map of the Internet, created by Jon Postel in 1982

Postel started work at UCLA on 23 December 1969 as a Postgraduate Research Engineer (I) where he was involved in early work on the ARPANET. He was involved in the development of the Internet domain system and, at his instigation, Vint Cerf and Bob Kahn developed a second set of protocols for handling data between networks, which is now known as Internet Protocol (IP).[7] Together with Cerf and Steve Crocker, Postel worked on implementing most of the ARPANET protocols.[8] Cerf would later become one of the principal designers of the TCP/IP standard,[8] which works because of the sentence known as Postel's Law.[9]

Postel worked with ARPANET until 24 August 1973 when he left to join MITRE Corporation. He assisted with Network Information Center which was being set up at SRI by Elizabeth Feinler. In March 1977, he joined the Information Sciences Institute at the University of Southern California as a research scientist.[10]

Postel was the RFC Editor from 1969 until his death, and wrote and edited many important RFCs, including RFC 791, RFC 792 and RFC 793, which define the basic protocols of the Internet protocol suite, and RFC 2223, *Instructions to RFC Authors*. Between 1982 and 1984 Postel co-authored the RFCs which became the foundation of today's DNS (RFC 819, RFC 881, RFC 882 and RFC 920) which were joined in 1995 by RFC 1591 which he also co-wrote. In total, he wrote or co-authored more than 200 RFCs.

Postel served on the Internet Architecture Board and its predecessors for many years. He was the Director of the names and number assignment clearinghouse, the Internet Assigned Numbers Authority (IANA), from its inception. He was the first member of the Internet Society, and was on its Board of Trustees. He was the original and long-time .us Top-Level Domain administrator. He also managed the Los Nettos Network.

All of the above were part-time activities he assumed in conjunction with his primary position as Director of the Computer Networks Division, Division 7, of the Information Sciences Institute at the University of Southern California.[11]

DNS Root Authority test, U.S. response

On January 28, 1998, Postel, as a test, emailed eight of the twelve operators of Internet's regional root nameservers on his own authority and instructed them to reconfigure their servers,[12] changing the root zone server from then SAIC subsidiary Network Solutions (NSI)'s A.ROOT-SERVERS.NET (198.41.0.4) to IANA's DNSROOT.IANA.ORG (198.32.1.98). The operators complied with Postel's instructions, thus dividing control of Internet naming between the non-government operators with IANA and the 4 remaining U.S. Government roots at NASA, DoD, and BRL with NSI. Though usage of the Internet was not interrupted, he soon received orders from senior government officials to undo this change,[13] which he did.[14] Within a week, the US NTIA issued *A proposal to improve technical management of Internet names and addresses*, including changes to authority over the Internet DNS root zone,[15] which ultimately, and controversially,[16] increased U.S. control.[17]

Legacy

On October 16, 1998, Postel died of complications from heart surgery in Los Angeles, nine months after the DNS Root Authority incident. He was recovering from a surgery to replace a leaking heart valve.[18]

The significance of Jon Postel's contributions to building the Internet, both technical and personal, were such that a memorial recollection of his life forms part of the core technical literature sequence of the Internet in the form of RFC 2468 "I Remember IANA", written by Vinton Cerf.

Another tribute "Working with Jon Tribute delivered at UCLA, October 30, 1998" RFC2441 , was written by D. Cohen.

Postel's law

Main article: Postel's law

Perhaps his most famous legacy is from RFC 760, which includes a robustness principle often called *Postel's law*: "an implementation should be

Perhaps his most famous legacy is from RFC 760, which includes a robustness principle often called Postel's law: "an implementation should be conservative in its sending behavior, and liberal in its receiving behavior" (reworded in RFC 1122 as "Be liberal in what you accept, and conservative in what you send").

JON POSTEL, INTERNET PIONEER, DIES AT 55 AFTER HEART SURGERY

Jon Postel, an Internet pioneer who wielded enormous influence managing technical details of the global computer network, died Oct. 16 in Los Angeles of complications from heart surgery. He was 55.

Postel, considered by the Clinton administration to be a crucial player in the future of the Internet, died while recovering from surgery to replace a leaking heart valve, said Vinton Cerf, a senior vice president for MCI Worldcom Inc., who worked closely with Postel.

Postel's death comes at a critical juncture for the Internet, with the federal government in the midst of largely turning over management of the worldwide network to a nonprofit group that Postel helped organize.

Although Postel was hardly known outside high-tech circles, his role as director of the Internet Assigned Numbers Authority allowed the Internet to match unique numerical addresses for computers on the global network with its millions of Web addresses.

The British magazine The Economist once dubbed Postel "god" of the Internet.

Earlier this year, Postel drew sharp criticism but demonstrated his influence when he redirected half the Internet's 12 directory-information computers to his own system. He told federal officials afterward he was running a test to see how smoothly such a transition could be made.

A researcher at the University of Maryland at College Park, which controls one of those computers, told The Washington Post: "If Jon asks us to point somewhere else, we'll do it. He is the authority here."

Cerf said Postel underwent a heart-valve replacement in 1991, but the replacement value started to leak about 10 days ago. He was hospitalized for surgery and was recovering when he died.

Cerf said Postel is survived by a brother.

Remembrance

A long time ago, in a network, far far away, a great adventure took place!

Out of the chaos of new ideas for communication, the experiments, the tentative designs, and crucible of testing, there emerged a cornucopia of networks. Beginning with the ARPANET, an endless stream of networks evolved, and ultimately were interlinked to become the Internet. Someone had to keep track of all the protocols, the identifiers, networks and addresses and ultimately the names of all the things in the networked universe. And someone had to keep track of all the information that erupted with volcanic force from the intensity of the debates and discussions and endless invention that has continued unabated for 30 years. That someone was Jonathan B. Postel, our Internet Assigned Numbers Authority, friend, engineer, confidant, leader, icon, and now, first of the giants to depart from our midst.

Jon, our beloved IANA, is gone. Even as I write these words I cannot quite grasp this stark fact. We had almost lost him once before in 1991. Surely we knew he was at risk as are we all. But he had been our rock, the foundation on which our every web search and email was built, always there to mediate the random dispute, to remind us when our documentation did not do justice to its subject, to make difficult decisions with apparent ease, and to consult when careful consideration was needed. We will survive our loss and we will remember. He has left a monumental legacy for all Internauts to

contemplate. Steadfast service for decades, moving when others seemed paralyzed, always finding the right course in a complex minefield of technical and sometimes political obstacles.

Jon and I went to the same high school, Van Nuys High, in the San Fernando Valley north of Los Angeles. But we were in different classes and I really didn't know him then. Our real meeting came at UCLA when we became a part of a group of graduate students working for Professor Leonard Kleinrock on the ARPANET project. Steve Crocker was another of the Van Nuys crowd who was part of the team and led the development of the first host-host protocols for the ARPANET. When Steve invented the idea of the Request for Comments series, Jon became the instant editor. When we needed to keep track of all the hosts and protocol identifiers, Jon volunteered to be the Numbers Czar and later the IANA once the Internet was in place.

Jon was a founding member of the Internet Architecture Board and served continuously from its founding to the present. He was the FIRST individual member of the Internet Society I know, because he and Steve Wolff raced to see who could fill out the application forms and make payment first and Jon won. He served as a trustee of the Internet Society. He was the custodian of the .US domain, a founder of the Los Nettos Internet service, and, by the way, managed the networking research division of USC Information Sciences Institute.

Jon loved the outdoors. I know he used to enjoy backpacking in the high Sierras around Yosemite. Bearded and sandaled, Jon was our resident hippie-patriarch at UCLA. He was a private person but fully capable of engaging photon torpedoes and going to battle stations in a good engineering argument. And he could be stubborn beyond all expectation. He could have outwaited the Sphinx in a staring contest, I think.

Jon inspired loyalty and steadfast devotion among his friends and his colleagues. For me, he personified the words "selfless service". For nearly 30 years, Jon has served us all, taken little in return, indeed sometimes receiving abuse when he should have received our deepest appreciation. It was particularly gratifying at the last

Internet Society meeting in Geneva to see Jon receive the Silver Medal of the International Telecommunications Union. It is an award generally reserved for Heads of State, but I can think of no one more deserving of global recognition for his contributions.

While it seems almost impossible to avoid feeling an enormous sense of loss, as if a yawning gap in our networked universe had opened up and swallowed our friend, I must tell you that I am comforted as I contemplate what Jon has wrought. He leaves a legacy of edited documents that tell our collective Internet story, including not only

the technical but also the poetic and whimsical as well. He completed the incorporation of a successor to his service as IANA and leaves a lasting legacy of service to the community in that role. His memory is rich and vibrant and will not fade from our collective consciousness. "What would Jon have done?", we will think, as we wrestle in the days ahead with the problems Jon kept so well tamed for so many years.

There will almost surely be many memorials to Jon's monumental service to the Internet Community. As current chairman of the Internet Society, I pledge to establish an award in Jon's name to recognize long-standing service to the community, the Jonathan B. Postel Service Award, which will be awarded to Jon posthumously as its first recipient.

If Jon were here, I am sure he would urge us not to mourn his passing but to celebrate his life and his contributions. He would remind us that there is still much work to be done and that we now have the responsibility and the opportunity to do our part. I doubt that anyone could possibly duplicate his record, but it stands as a measure of one man's astonishing contribution to a community he knew and loved.

Security Considerations

Security issues are not relevant to this Remembrance.

Author's Address

Vinton G. Cerf

MCI

The announcement was made November 30 by Joseph Bannister, Ph.D., Director of the Computer Networks Division at the University of Southern Californiaís Information Sciences Institute and a longtime collaborator with Internet pioneer Dr. Postel. Bannister has served as interim director of **the center since it opened April 20, 1999, six months after Postelís death October 16, 1998.**

Touch Named Director of ISI’s Postel Center

DECEMBER 11, 2000

Joseph D. Touch

Joseph D. Touch has been named the director of the Postel Center for Experimental Networking at the School of Engineering’s Information Sciences Institute (ISI). Touch will be responsible for the daily operation and long-range direction of the center. He will set up the center’s laboratory, work with industrial and individual sponsors, chair the scholar selection committees and determine policy and direction. Touch, who has been at ISI since 1992, is a project leader and research assistant professor of computer science. He has also worked at Bellcore, GTE Labs and SEI. His research interests include virtual networks, network architecture, optical networks and protocol performance.

The Postel Center for Experimental Networking was established in 1999 to commemorate Jon Postel’s pioneering contributions to the development of the Internet. Postel, who died in 1998, was the director of ISI’s computer networks division and created the Internet’s address system. For three decades he played a pivotal role in the technical management and administration of the Internet as director of the Assigned Numbers Authority. **The center has been endowed by Cisco Systems, Centergate and Sun Microsystems, as well as a number of private individuals**. Its mission is to promote Postel’s tradition of applied research in service to the Internet community, including providing facilities, funding and support for distinguished visiting scholars and graduate fellows to collaborate with ISI researchers.

His research interests include virtual networks, network architecture, optical networks and protocol performance.

Joseph D. Touch

The Postel Center for Experimental Networking was established in 1999 to commemorate Jon Postel's pioneering contributions to the development of the Internet. Postel, who died in 1998, was the director of ISI's computer networks division and created the Internet's address system. For three decades he played a pivotal role in the technical management and administration of the Internet as director of the Assigned Numbers Authority. The center has been endowed by Cisco Systems, Centergate and Sun Microsystems, as well as a number of private individuals. Its mission is to promote Postel's tradition of applied research in service to the Internet community, including providing facilities, funding and support for distinguished visiting scholars and graduate fellows to collaborate with ISI researchers.

1998 (Oct 18) - Washington Post - JON POSTEL, INTERNET PIONEER, DIES AT 55 AFTER HEART SURGERY

[HN01GN][GDrive]

Jon Postel, an Internet pioneer who wielded enormous influence managing technical details of the global computer network, died Oct. 16 in Los Angeles of complications from heart surgery. He was 55.

Postel, considered by the Clinton administration to be a crucial player in the future of the Internet, died while recovering from surgery to replace a leaking heart valve, said Vinton Cerf, a senior vice president for MCI Worldcom Inc., who worked closely with Postel.

Postel's death comes at a critical juncture for the Internet, with the federal government in the midst of largely turning over management of the worldwide network to a nonprofit group that Postel helped organize.

Although Postel was hardly known outside high-tech circles, his role as director of the Internet Assigned Numbers Authority allowed the Internet to match unique numerical addresses for computers on the global network with its millions of Web addresses.

The British magazine The Economist once dubbed Postel "god" of the Internet.

Earlier this year, Postel drew sharp criticism but demonstrated his influence when he redirected half the Internet's 12 directory-information computers to his own system. He told federal officials afterward he was running a test to see how smoothly such a transition could be made.

A researcher at the University of Maryland at College Park, which controls one of those computers, told The Washington Post: "If Jon asks us to point somewhere else, we'll do it. He is the authority here."

Cerf said Postel underwent a heart-valve replacement in 1991, but the replacement value started to leak about 10 days ago. He was hospitalized for surgery and was recovering when he died.

Cerf said Postel is survived by a brother.

Richard Preston (born August 5, 1954) is a writer for The New Yorker and bestselling author who has written books about infectious disease, bioterrorism, redwoods and other subjects, as well as fiction. Whether journalistic or fictional, his writings are based on extensive background research and interviews.

Biography

Preston was born in Cambridge, Massachusetts. He graduated Wellesley High School in Massachusetts in 1972 and attended Pomona College in Claremont, California. He earned a Ph.D. in English from Princeton University in 1983.

His 1992 New Yorker article "Crisis in the Hot Zone" was expanded into his breakout book, The Hot Zone (1994). It is classified as a "non-fiction thriller" about ebolaviruses. He came to know about ebola through such contacts as U.S. Army researchers [**Dr. Clarence James Peters (born 1940)**] and [Dr.] Nancy Jaax. His fascination began during a visit to Africa where he was an eyewitness to epidemics. **The book served as the (very loose) basis of the Hollywood movie Outbreak(1995) about military machinations surrounding a fictional "Motaba virus".**

Preston's novel The Cobra Event (1998), about a terrorism release of a fictional virus combining various qualities of different diseases upon New York City, alarmed even then-President Bill Clinton who, shortly after reading it, instigated a review of bio-terror threats to the U.S.[1] The book strove to tell a fast-paced thriller narrative within the bounds of well-researched bio-terrorism possibility, and was reportedly pressed upon Clinton by a molecular biologist when he was attending a Renaissance Weekend event.[2]

The Demon in the Freezer (2002) covers the story of the eradication of smallpox, perhaps the most destructive virus to have plagued mankind. It details the survival of the virus in research labs and bio-weapon programs of Russia and other nations, despite its eradication in the human population. The narrative continues with anthrax, a bacterial disease of cattle and humans, used in the 2001 anthrax attacks.

First Light and American Steel are non-fiction books addressing astrophysics and the steel industry. First Light centers around the history of the Hale telescope on Palomar Mountain, and the astronomers who work there. American Steel chronicles the history of the Nucor steel company, and focuses on its newest steel plant in Indiana, whose success depends on a new steel-sheet making machine engineered in West Germany.

Preston's personal hobby of recreational tree climbing is introduced in The Wild Trees (2007).[3] His climbing experience likely led him to write about the largest known redwoods like Lost Monarch in the Grove of Titans, or Iluvatar, described in that book along with delicate forest canopy ecosystems.

Preston's Panic in Level 4: Cannibals, Killer Viruses, and Other Journeys to the Edge of Science is a collection of essays related to his experiences researching his previous books.

In November 2009, Preston was selected by Harper-Collins and the Michael Crichton estate to complete his unfinished novel Micro after Crichton's death in November 2008. The book was released on November 22, 2011. Approximately a third of Micro was completed by Crichton. Preston completed the book according to the author's remaining outline, notes, and research.[4]

In 2016, Preston served as the Bedell Distinguished Visiting Professor at the University of Iowa's Nonfiction Writing Program[5] where he judged the prestigious Iowa Prize in Literary Nonfiction.

Preston resides in Hopewell, New Jersey with his wife, Michelle, and their two daughters and one son.[6] He is also the brother of best-selling author Douglas Preston.

1999 (July 17) - The New Yorker, July 12, 1999, pp. 44-61. : "THE DEMON IN THE FREEZER" BY RICHARD PRESTON

"THE DEMON IN THE FREEZER : How smallpox, a disease of officially eradicated twenty years ago, became the biggest bioterrorist threat we now face."

http://cryptome.org/smallpox-wmd.htm / 1999-07-17-cryptome-org-the-demon-in-the-freezer-new-yorker / https://drive.google.com/file/d/1UiAh4eB5WK38tXww4rT1BVbSlOVVE2mP/view?usp=sharing

THE smallpox virus first became entangled with the human species somewhere between three thousand and twelve thousand years ago -- possibly in Egypt at the time of the Pharaohs. Somewhere on earth at roughly that time, the virus jumped out of an unknown animal into its first human victim, and began to spread. Viruses are parasites that multiply inside the cells of their hosts, and they are the smallest life forms. Smallpox developed a deep affinity for human beings. It is thought to have killed more people than any other infectious disease, including the Black Death of the Middle Ages. It was declared eradicated

from the human species in 1979, after a twelve-year effort by a team of doctors and health workers from the World Health Organization. Smallpox now exists only in laboratories.

Smallpox is explosively contagious, and it travels through the air. Virus particles in the mouth become airborne when the host talks. If you inhale a single particle of smallpox, you can come down with the disease. After you've been infected, there is a typical incubation period of ten days. During that time, you feel normal. Then the illness hits with a spike of fever, a backache, and vomiting, and a bit later tiny red spots appear all over the body. The spots turn into blisters, called pustules, and the pustules enlarge, filling with pressurized opalescent pus. The eruption of pustules is sometimes called the splitting of the dermis. The skin doesn't break, but splits horizontally, tearing away from its underlayers. The pustules become hard, bloated sacs the size of peas, encasing the body with pus, and the skin resembles a cobbled stone street.

The pain of the splitting is extraordinary. People lose the ability to speak, and their eyes can squeeze shut with pustules, but they remain alert. Death comes with a breathing arrest or a heart attack or shock or an immune-system storm, though exactly how smallpox kills a person is not known. There are many mysteries about the smallpox virus. Since the seventeenth century, doctors have understood that if the pustules merge into sheets across the body the victim will usually die: the virus has split the whole skin. If the victim survives, the pustules turn into scabs and fall off, leaving scars. This is known as ordinary smallpox.

Some people develop extreme smallpox, which is loosely called black pox. Doctors separate black pox into two forms -- flat smallpox and hemorrhagic smallpox. In a case of flat smallpox, the skin remains smooth and doesn't pustulate, but it darkens until it looks charred, and it can slip off the body in sheets. In hemorrhagic smallpox, black, unclotted blood oozes or runs from the mouth and other body orifices. Black pox is close to a hundred per cent fatal. If any sign of it appears in the body, the victim will almost certainly die. In the bloody cases, the virus destroys the linings of the throat, the stomach, the intestines, the rectum, and the vagina, and these membranes disintegrate. Fatal smallpox can destroy the body's entire skin -- both the exterior skin and the interior skin that lines the passages of the body.

Smallpox virus's scientific name is variola. It means "spotted" in Latin, and it was given to the disease by a medieval bishop. The virus, as a life form, comes in two subspecies: Variola minor and Variola major. Minor is a weak mutant, and was first described in 1863 by doctors in Jamaica. People usually survive it. Classic major kills one out of three people if they haven't been vaccinated or if they've lost their immunity. The death rate with major can go higher -- how much higher no one knows. Variola major killed half of its victims in an outbreak in Canada in 1924, and presumably many of them developed black pox. Smallpox is less contagious than measles but more contagious than mumps. It tends to go around until it has infected nearly everyone.

Most people today have no immunity to smallpox. The vaccine begins to wear off in many people after ten years. Mass vaccination for smallpox came to a worldwide halt around twenty-five years ago. There is now very little smallpox vaccine on hand in the United States or anywhere else in the world. The World Health Organization once had ten million doses of the vaccine in storage in Geneva, Switzerland, but in 1990 an advisory committee recommended that most of it be destroyed, feeling that smallpox was longer a threat. Nine and a half million doses are assumed to have been cooked in an oven, leaving the W.H.O. with a total supply of half a million doses -- one dose of smallpox vaccine for every twelve thousand people on earth. A recent survey by the W.H.O. revealed that there is only one factory in the world that has recently made even a small quantity of the vaccine, and there may be no factory capable of making sizable amounts. The vaccine was discovered in the age of Thomas Jefferson, and making a lot of it would seem simple, but so far the United States government has been unable to get any made at all. Variola virus is now classified as a Biosafety Level 4 hot agent -- the most dangerous kind of virus -- because it is lethal, airborne, and highly contagious, and is now exotic to the human species, and there is not enough vaccine to stop an outbreak. Experts feel that the appearance of a single case of smallpox anywhere on earth would be a global medical emergency.

At the present time, smallpox lives officially in only two repositories on the planet. One repository is in the United States, in a freezer at the headquarters of the federal Centers for Disease Control and Prevention, in Atlanta -- the C.D.C. The other official smallpox repository is in a freezer at a Russian virology institute called Vector, also known as the State Research Institute of Virology and Biotechnology, which is situated outside the city of Novosibirsk, in Siberia. Vector is a huge, financially troubled former virus-weapons-development facility -- a kind of decayed Los Alamos of viruses -- which is trying to convert to peaceful enterprises.

There is a growing suspicion among experts that the smallpox virus may also live unofficially in clandestine biowarfare laboratories in a number of countries around the world, including labs on military bases in Russia that are closed to outside observers. The Central Intelligence Agency has become deeply alarmed about smallpox. Since 1995, a number of leading American biologists and public-health doctors have been given classified national-security briefings on smallpox. They have been shown classified evidence that as recently as 1992 Russia had the apparent capability of launching strategic-weapons-grade smallpox in special biological warheads on giant SS-18 intercontinental missiles that were targeted on the major cities of the United States. In the summer of last year, North Korea fired a ballistic missile over Japan in a test, and the missile fell into the sea. Some knowledgeable observers thought that the missile could have been designed to carry a biologic warhead. If it had carried smallpox and landed in Japan, it could have devastated Japan's population: Japan has almost no smallpox vaccine on hand and its government seems to have no ability to deal with a biological attack. The United States government keeps a list of nations and groups that it suspects either have clandestine stocks of smallpox or seem to be trying to buy or steal the virus. The list is classified, but it is said to include Russia, China, India, Pakistan, Israel, North Korea, Iraq, Iran, Cuba, and Serbia. The list may also include the terrorist organization of Osama bin Laden and, possibly, the Aum Shinrikyo sect of Japan -- a quasi-religious group that had Ph.D. biologists as members and a belief that an apocalyptic war will bring them worldwide power. Aum members released nerve gas in the Tokyo subway in 1995, and, as the year 2000 approaches, the group is still active in Japan and in Russia. In any case, the idea that smallpox lives in only two freezers was never anything more than a comfortable fiction. No one knows exactly who has smallpox today, or where they keep the virus, or what they intend to do with it.

THE man who is most widely credited with the eradication of smallpox from the human species is a doctor named Donald Ainslie Henderson. Everyone calls him D. A. Henderson. He was the director of the World Health Organization's Smallpox Eradication Unit from its inception, in 1966, to 1977, just before the last case occurred. "I'm one of many in the eradication," Henderson said to me once. "There's Frank Fenner, there's Isao Arita, Bill Foege, Nicole Grasset, Zdenek Jezek, Jock Copland, John Wickett -- I could come up with fifty names. Let alone the tens of thousands who worked in the infected countries." Nevertheless, Henderson ran it. Smallpox killed at least three hundred million people in the twentieth century. During that time, humanity was largely immune to smallpox, which is not the case today. When D. A. Henderson arrived on the scene in 1966, two million people a year were dying of smallpox. In the years since the eradication effort began, Henderson and his team have effectively saved more than fifty million lives. This could be the most impressive achievement in the history of medicine. Henderson and his colleagues, however, have never received the Nobel Prize for their work.

D. A. Henderson is now a professor at the Johns Hopkins School of Public Health. He is the founder and the director of the Johns Hopkins Center for Civilian Biodefense Studies, a think tank that considers what might be done to protect the American population during a biological event. The term "biological event" hardly existed two years ago, but it is now used by emergency planners and by the F.B.I. to mean a terrorist attack with a bioweapon -- an unnatural event, caused by human intent.

Henderson lives with his wife in a large brick house in Baltimore. I arrived there on a cold, drizzly Saturday, and he ambled to the door. Henderson is an imposing man, six feet two inches tall. He is seventy years old. He has broad shoulders and a broad, seamed, angular face, pointed ears that stick out at angles from his head, a brush of gray hair, metal-framed eyeglasses, sharp blue eyes, and an easygoing voice that can flash with calculation. He was wearing a red checked shirt, with suspenders that held up Saturday slacks.

"In the last ten days, we've had fourteen different anthrax scares," he remarked in an offhand way as we stood in the front hallway of his house and he loomed over me. He has a top-secret-level national-security clearance, and he hears about little bioterror events that don't get noticed by the media. He went on to say, "Everybody and his brother is threatening to use anthrax. This week, it happened in Atlanta, in Washington, D.C., in Michigan, and in California. It's largely hoaxes. Of course, a real bioterror event is going to happen one of these days."

We settled into easy chairs in the family room. The walls and shelves of the room were crowded with African and Asian sculptures and wooden Ethiopian crosses, which he had picked up in his global hunt for smallpox. A Japanese garden was visible through sliding-glass doors.

We ate ham and roast-beef sandwiches, and drank Molson Ice beers. Henderson bit into a sandwich and chewed thoughtfully. Then he said, "Often, you get a worried look on your face, with the first signs of rash. We speak of the 'worried face' of smallpox. That face is a diagnostic sign. The rash comes up all at once. It's more dense on the face and the extremities. That's how you can tell smallpox from chicken pox. With chicken pox, the rash crops up over a period of days, and it's more dense on the chest and trunk of the body. Smallpox pustules have a dimple, a dent in the center. Doctors say that the pustules have a 'shotty' feel, like shotgun pellets. You can roll them between your fingertips under the skin."

"How many doctors could recognize smallpox today?" I asked.

"Virtually none. Smallpox takes forms that even I can't diagnose. And I wrote the textbook." He is a co-author of "Smallpox and Its Eradication," a large book in red covers, which experts call the Big Red Book of Smallpox. It was supposed to be the final word on smallpox-the tombstone of the virus.

ON February 15,1972, a thirty-eight-year-old Muslim clergyman returned to his home town of Damnjane, in Kosovo, Yugoslavia, after he'd been on a pilgrimage to Mecca, stopping at holy sites in Iraq. I will call him the Pilgrim. A photograph of the Pilgrim shows a man who looks well educated, has an intelligent face, and is wearing a clipped mustache and a beret. He had travelled by bus for his entire journey. The morning after his return home, he woke up feeling achy. At first, he thought he was tired from the long bus ride, but then he realized that he had caught a bug. He shivered for a day or two, and developed a red rash brought on by his fever, but quickly recovered. He had been vaccinated for smallpox two months earlier. Indeed, the Yugoslav medical authorities had been vaccinating the population of Yugoslavia relentlessly for more than fifty years, and the country was considered to be thoroughly immunized. The last case of smallpox in Yugoslavia had occurred in 1930.

The Pilgrim's family members and friends came to visit him. They wanted to hear about his trip, and he enjoyed telling them about it. Meanwhile, variola particles were leaking out of raw spots in the back of his throat and mixing with his saliva. When he spoke, tiny droplets of saliva, too small to be seen, drifted around him in a droplet cloud. If the person is throwing off a lethal virus, the cloud becomes a hot zone that can extend ten feet in all directions. Although the raw spots in the Pilgrim's throat amounted to a tiny surface of virus emission, smaller than a postage stamp, in a biological sense it was as hot as the surface of the sun, and it put enough smallpox into the air to paralyze Yugoslavia.

Variola particles are built to survive in the air. They are rounded-off rectangles that have a knobby, patterned surface-a gnarly hand-grenade look. Some experts call the particles bricks. The whole brick is made of a hundred different proteins, assembled and interlocked in a three-dimensional puzzle, which nobody has ever figured out. Virus experts feel that the structure of a smallpox particle is almost breathtakingly beautiful and deeply mathematical-one of the unexplored wonders of the viral universe. The structure protects the virus's genetic material: a long strand of DNA coiled in the center of the brick.

Pox bricks are the largest viruses. If a smallpox brick were the size of a real brick then a cold-virus particle would be a blueberry sitting on the brick. But smallpox particles are still extremely small; about three million smallpox bricks laid down in rows would pave the period at the end of this sentence. A smallpox victim emits several bricks in each invisible droplet of saliva that spews into the air when the person speaks or coughs. When an airborne smallpox particle lands on a mucus membrane in someone's throat or lung, it sticks. It enters a cell and begins to make copies of itself. For one to three weeks, the virus spreads from cell to cell, amplifying silently in the body. No one has discovered exactly where the virus z hides during its incubation phase. Probably it gets into the lymph cells, confusing the immune system, and victims are said to experience terrible dreams.

On February 21st, when the Pilgrim had been feeling achy for almost a week, a thirty-year-old man, a schoolteacher, who is known to experts as Ljatif M., arrived in Djakovica, a few miles from the Pilgrim's town, to enroll in the Higher Institute of Education. Doctors who later investigated the schoolteacher's case never found out how he had come in contact with the Pilgrim. One of them must have ended up in the other's town. Possibly they stood next to each other in a shop-something like that.

On March 3rd, Ljatif developed a fever. Two days later, he went to a local medical center, where doctors gave him penicillin for his fever. Antibiotics have no effect on a virus. Then his skin broke with dark spots, and he may have developed a worried face. He felt worse, and a few days later his brother took him by bus to a hospital in the town of Cacak, about a hundred miles away. The dark spots were by this time merging into blackened, mottled splashes, which the doctors in Cacak didn't recognize. Ljatif became sicker. Finally, he was transferred by ambulance to Belgrade, where he was admitted to the Dermatology and Venereal Diseases Department of the city's main hospital. By then, his skin may have turned almost black in patches. We don't have access to his clinical reports, so I am describing a generalized extreme smallpox of the kind Ljatif had.

Inside the cells of the host, smallpox bricks pile up as if they were coming off a production line. Some of the particles develop tails. The tails are pieces of the cell's protein, which the virus steals from the cell for its own use. The tailed smallpox particles look like comets or spermatozoa. They begin to twist and wriggle, and they corkscrew through the cell, propelled by their tails toward the cell's outer membrane. You can see them with a microscope, thrashing with the same furious drive as sperm. They bump up against the inside of the cell membrane, and their heads make lumps, and the cell horripilates. Then something wonderful happens. Finger tubes begin to extend from the cell. The tubes grow longer. The cell turns into a Koosh ball. Inside each finger tube is a smallpox comet. The fingers lengthen until they touch and join nearby cells, and the smallpox comets squirm through the finger tubes into the next cell. The comets are protected from attack by the immune system, because they stay inside the finger tubes, where antibodies and killer white blood cells can't reach them. Then the Koosh ball explodes. Out pour heaps of bricks that don't have tails. These smallpox particles are wrapped in a special armor, like hand grenades. They float away, still protected by their armor, and they stick to other cells and go inside them, and those cells turn into Koosh balls. Each infected cell releases up to a hundred thousand virus particles, and they are added to the quadrillions of particles replicating in the universe of the ruined host.

Ljatif's skin had become blackened, mottled, and silky to the touch, and sheets of small blood blisters may have peppered his face. In a case of black pox, variola shocks the immune system so that it can't produce pus. Small blood vessels were leaking and breaking in his skin, and blood was seeping under the

variola shocks the immune system so that it can't produce pus. Small blood vessels were leaking and breaking in his skin, and blood was seeping under the surface. His skin had developed large areas of continuous bruises.

On March 9th, the Belgrade doctors showed Ljatif to students and staff as a case that demonstrated an unusual reaction to penicillin. (In fact, a very bad reaction to penicillin can look like this.) Ljatif's eyes may have turned dark red. In hemorrhagic smallpox, one or two large hemorrhages appear in each eye, in the white encircling the iris, making the eyes look as if they could sag or leak blood. The eyes never do leak, but the blood in the eyes darkens, until the whites can sometimes seem almost black.

During the day of March 10th, Ljatif suffered catastrophic hemorrhages into the intestines. His intestines filled up with blood, and he expelled quarts of it, staining the sheets black, and he developed grave anemia from blood loss. For some unknown reason, black-pox patients remain conscious, in a kind of paralyzed shock, and they seem acutely aware of what is happening nearly up to the point of death -- "a peculiar state of apprehension and mental alertness that were said to be unlike the manifestations of any other infectious disease," in the words of the Big Red Book of Smallpox. We can imagine that Ljatif was extremely frightened and witnessed his hemorrhages with a sense that his insides were coming apart. During the final phase of a smallpox intestinal bleedout, the lining of the intestines or the rectum can slip off. The lining is expelled through the anus, coming out in pieces or in lengths of tube. This bloody tissue is known as a tubular cast. When a smallpox patient throws a tubular cast, death is imminent. Al1 we know about Ljatif is that his bleeds were unstoppable, that he was rushed to the Surgical Clinic of the Belgrade hospital, and that he died in the evening. The duty physician listed the cause of death as a bad reaction to penicillin.

"These hemorrhagic smallpox cases put an incredible amount of virus into the air," D. A. Henderson said. Some of the doctors and nurses who treated Ljatif were doomed. Indeed, Ljatif had seeded smallpox across Yugoslavia. Investigators later found that while he was in the hospital in Cacak he infected eight other patients and a nurse. The nurse died. One of the patients was a schoolboy, and he was sent home, where he broke with smallpox and infected his mother, and she died. In the Belgrade hospital, Ljatif infected twenty-seven more people, including seven nurses and doctors. Those victims infected five more people. Ljatif directly infected a total of thirty-eight people. They caught the virus by breathing the air near him. Eight of them died.

Meanwhile, the Pilgrim's smallpox travelled in waves through Yugoslavia. A rising tide of smallpox typically comes in fourteen-day waves -- a wave of cases, a lull down to zero, and then a much bigger wave, another lull down to zero, then a huge and terrifying wave. The waves reflect the incubation periods, or generations, of the virus. Each wave or generation is anywhere from ten to twenty times as large as the last, so the virus grows exponentially and explosively, gathering strength like some kind of biological tsunami. This is because each infected person infects an average of ten to twenty more people. By the end of March, 1972, more than a hundred and fifty cases had occurred.

The Pilgrim had long since recovered. He didn't even know that he had started the outbreak. By then, however, Yugoslav doctors knew that they were dealing with smallpox, and they sent an urgent cable to the World Health Organization, asking for help.

Luckily, Yugoslavia had an authoritarian Communist government, under Josip Broz Tito, and he exercised full emergency powers. His government mobilized the Army and imposed strong measures to stop people from travelling and spreading the virus. Villages were closed by the Army, roadblocks were thrown up, public meetings were prohibited, and hotels and apartment buildings were made into quarantine wards to hold people who had had contact with smallpox cases. Ten thousand people were locked up in these buildings by the Yugoslav military. The daily life of the country came to a shocked halt. At the same time, all the countries surrounding Yugoslavia closed their borders with it, to prevent any travellers from coming out. Yugoslavia was cut off from the world. There were twenty-five foci of smallpox in the country. The virus had leapfrogged from town to town, even though the population had been heavily vaccinated. The Yugoslav authorities, helped by the W.H.O., began a massive campaign to revaccinate every person in Yugoslavia against smallpox; the population was twenty-one million. "They gave eighteen million doses in ten days," D. A. Henderson said. A person's immunity begins to grow immediately after the vaccination; it takes full effect within a week.

At the beginning of April, Henderson flew to Belgrade, where he found government officials in a state of deep alarm. The officials expected to see thousands of blistered, dying, contagious people streaming into hospitals any day. Henderson sat down with the Minister of Health and examined the statistics. He plotted the cases on a time line, and now he could see the generations of smallpox -- one, two, three waves, each far larger than the previous one. Henderson had seen such waves appear many times before as smallpox rippled and amplified through human populations. Reading the viral surf with a practiced eye, he could see the start of the fourth wave. It was not climbing as steeply as he had expected. This meant that the waves had peaked. The outbreak was declining. Because of the military roadblocks, people weren't travelling, and the government was vaccinating everyone as fast as possible. "The outbreak is near an end," he declared to the Minister of Health. "I don't think you'll have more than ten additional cases." There were about a dozen: Henderson was right -- the fourth wave never really materialized. The outbreak had been started by one man with the shivers. It was ended by a military crackdown and vaccination for every citizen.

AT the present time, the United States' national stockpile of smallpox vaccine is a collection of four cardboard boxes that sit on a single pallet behind a chain-link fence inside a walk-in freezer in a warehouse in Lancaster County, Pennsylvania, near the Susquehanna River, at a facility owned by Wyeth-Ayerst Laboratories. The vaccine is slowly deteriorating. The Food and Drug Administration has put a hold on the smallpox vaccine, and right now no one can use it -- not even emergency personnel or key government leaders.

The vaccine is owned by the federal government and is managed by Wyeth-Ayerst, which is the company that made it, twenty-five to thirty years ago. It is stored in glass vials. The vials contain freeze-dried nuggets of live vaccinia virus. Vaccinia is a mild virus. When you are infected with it by vaccination, it causes a pustule to appear, and afterward you are immune to smallpox for some years. People who have been vaccinated have a circular scar the size of a nickel on their upper arm, left by the vaccinia-virus pustule they had in childhood after vaccination. Some adults can remember how much the pustule hurt.

People from Wyeth periodically open the boxes and send some of the vials out for testing, to see how the vaccine is doing. The vials once held fifteen million good doses, but now moisture has invaded some of them. The nuggets are normally dry and white in color, but when moisture invades they turn brown and look sticky, and the vaccine may be weakened. The vaccine was made by a traditional method: the manufacturer had a farm where calves were raised. The calves' bellies were scratched with vaccinia virus, and their bellies developed pustules. Then the calves were killed and hung up on hooks, the blood was drained out of them, and the pustules were scraped with a knife. The resulting pus was freeze-dried. The vaccine is dried calf pus. According to one virologist who examined it under a microscope, "It looks like nose snot. It's all hair and wads of crap." It was a good vaccine for its time, but the F.D.A. would never clear it for general use today except in a national emergency. Furthermore, some people have bad or fatal reactions to the vaccine. There is an antidote, but the supplies of it have turned strangely pink, and the F.D.A. has put a hold on the use of these supplies, too.

D. A. Henderson believes that in practice doctors could obtain about seven million doses of vaccine from the vials. Unaccountably, most of the vaccine has not recently been tested for potency, so it has not been absolutely proved to work. The experts believe that it would work, but there still isn't enough.

Henderson explained the problem this way: "If there's a bioterror event, and someone releases enough smallpox to create a hundred cases -- let's say in the Baltimore area -- it would be a national emergency. The demand for vaccine would be beyond all belief." In Yugoslavia in 1972, the outbreak was started by one man, and eighteen million doses of vaccine were needed -- one for almost every person in the country.

"That first wave after the bioterror event could be a hundred people with smallpox," Henderson said. "It takes two weeks after exposure before doctors can diagnose smallpox. Meanwhile, those hundred people will give smallpox to a thousand or two thousand people. That's the second wave. Some of those first hundred people will go to other cities -- to Washington, to New York, all over. So the second wave will include cases in other American cities, and probably in foreign countries. By then, it'll be too late to treat them, and we'll lose the second wave. We'll be well into the third wave -- ten to twenty thousand people with smallpox -- before we can really start vaccinating people. By then, we'll begin to pick up so many cases in the Baltimore area that we won't be able to track cases, and we'll just have to vaccinate everybody around Baltimore. A lot of people in Baltimore work in Washington. And so you're going to have a whole lot of people in Washington with smallpox. You can see the deal. Immediately, you would have to vaccinate Washington." Henderson thinks that a hundred million doses of vaccine would be needed in the United States alone to stop a surging outbreak triggered by a hundred initial cases of smallpox from a bioterror event. That much vaccine could be stored in the space occupied by a one-car garage.

Raindrops splattered on a wooden deck in Henderson's garden, and the room grew dark, until it was a pool of shadows full of African masks. Henderson's voice came out of the gloom. He didn't bother to get up and turn on the lights. He said, "The way air travel is now, about six weeks would be enough time to seed cases around the world. Dropping an atomic bomb could cause casualties in a specific area, but dropping smallpox could engulf the world."

Henderson passionately wants to get rid of the virus. "What we need to do is create a general moral climate where smallpox is considered too morally reprehensible to be used as a weapon. That would make the possession of smallpox in a laboratory, anywhere, effectively a crime against humanity. The likelihood that it would be used as a weapon is diminished by a global commitment to destroy it. How much it is diminished I don't know. But it adds a level of safety."

IN the late seventeen-hundreds, the English country doctor Edward Jenner noticed that dairymaids who had contracted cowpox from cows seemed to be protected from catching smallpox, and he thought he would do an experiment. Cowpox (it probably lives in rodents, and only occasionally infects cows) produced a mild disease. On May 14, 1796, Jenner scratched the arm of a boy named James Phipps, introducing into the boy's arm a droplet of cowpox pus that he'd taken from a blister on the hand of a dairy worker named Sarah Nelmes. A few months later, he scratched the boy's arm with deadly pus he had taken from a smallpox patient, and the boy didn't come down with smallpox. The boy had become immune. Jenner had discovered what he called vaccination, after the Latin word for cow. He saw the road to eradication clearly. In 1801, he wrote, "It now becomes too manifest to admit of controversy, that the annihilation of the Small Pox, the most dreadful scourge of the human species, must be the final result of this practice."

A Soviet epidemiologist, Viktor Zhdanov, deserves credit for kick-starting the modern effort. At the 1958 annual meeting of the World Health Assembly, in Minneapolis, he called for the global eradication of smallpox. He spoke passionately and logically, but the scientific community was skeptical. Many biologists held a common view that it was impossible to separate a wild microorganism from the ecological web it lived in. In 1965, President Lyndon Johnson endorsed the idea of smallpox eradication. It was a political move to help improve American-Soviet relations. D. A. Henderson was then the head of disease surveillance at the C.D.C. He was given an order to report to Geneva to head the W.H.O.'s new Smallpox Eradication Unit. He didn't want the job, but he was told that if he didn't take it he would have to resign from government service. He went to Geneva, where he formed a hand-picked team. "The World Health Assembly proposed a ten-year program, because Kennedy had said we could land a man on the moon in ten years," he recalled.

The team set a goal of vaccinating eighty per cent of the population of countries that harbored smallpox. Henderson says that from the beginning they had another idea as well, and it proved to be the key. The idea was to track smallpox outbreaks and vaccinate people in a ring around any outbreak. This is known as surveillance and ring vaccination. In order to throw a ring around smallpox, they had to know where the demon was moving at all times, and they started showing villagers photographs of a baby with smallpox, so that the villagers could recognize and report cases to the authorities.

Henderson's team needed a way of vaccinating people fast. They tried a machine called the Ped-o-Jet, which was operated by foot pedal. It could shoot jets of vaccine into the arms of thousands of people in a day, but it broke down. Then they tried a needle with two points. It was known as the bifurcated needle, and it looked like a tiny two-pronged fork. The points of the fork held a droplet of vaccine, and the needle was to be jabbed repeatedly into a person's arm. It could be used by a volunteer who had no medical training.

They discovered that the virus rose and fell in seasonal waves, like flu. This led to an idea to attack the virus with a ring assault when it was at its ebb. The virus was a wild organism that lived only in humans. It needed to find and invade a susceptible human every fourteen days or it would die. If each outbreak of the virus could be surrounded by a ring of immune people during the virus's low season, the virus would not be able to complete its fourteen-day life cycle. It would be cut off, unable to move to the next human host, and its chain of infection would be broken.

The ring had to be tight. If it developed a leak, smallpox would blow out. In January, 1975, smallpox blew out in Bangladesh, after the eradicators thought they were on the verge of stopping it everywhere in Asia. Variola major swept through more than five hundred towns and villages. Henderson began shuttling between Geneva and Bangladesh, and in April of that year, when things were still not under control, he visited the Infectious Disease Hospital in Dacca, the nation's capital. He wanted to do rounds in a smallpox ward. "I went down the rows of beds," he told me. There were seventy or eighty people, and half of them were dying. "There is nothing you can do for any of these patients. They were afraid to move. There were a lot of flies crawling all over the place. My God, they talk about the odor of smallpox. It is an odd smell, not like anything else."

The skin gives off gases. "It's a sickly odor, like rotting flesh, but it's not decay, because the skin remains sealed and the pus isn't leaking out," Henderson said. "That smell is one of the mysteries of smallpox. No one knows what it is. I was with this British guy, Nick Ward, M.D. He had worked in Africa -- he was a tough guy. At the end, he stood by a fence looking at the ground. Finally, he said to me, 'I don't know that I could go through another situation like that again."'

Nicholas Ward, who now lives in France, remembered that moment. "I've spent a fair amount of my life working with tropical diseases, and I can truly say there is nothing so awful as a case of smallpox, particularly the type where a person becomes a bloody mess," he said. He knew the odor. "I would have a shrewd idea of a diagnosis after walking into a home. I could smell it."

Henderson and his team mounted ring vaccinations across Bangladesh, and they traced cases and contacts, trying to surround the life form. Finally, in the fall of 1975, they cornered variola on an island off the coast of Bangladesh. It was a marshy, poor place called Bhola Island, and there, on October 16th, a three-year-old girl named Rahima Banu broke with the last case of naturally occurring Variola major anywhere on earth. She survived. Rahima Banu would be twenty-seven years old today; researchers have lost track of her. Doctors from the Smallpox Eradication Unit collected six of the girl's pustules after they had dried into scabs, peeling them off her skin gently, with tweezers. Two years later, on October 26, 1977, the last natural case of the mild type of smallpox, Variola minor, popped up in a cook in Somalia named Ali Maow Maalin. He survived, and the last ring tightened around variola, and its life cycle

stopped.

THE headquarters of the Centers for Disease Control, in Atlanta, is a jumble of old and new buildings, joined by elevated walkways, which give the place the feel of a maze. The buildings sit along Clifton Road, an artery that winds through green neighborhoods in the northeastern part of Atlanta. I arrived at the C.D.C. On a perfect day in spring. Changeable clouds marched across a deep sky, and oak trees were shedding green flowers. Across the street from the entrance, a blue jay screamed in a pine tree, and the branches glittered in the sun, throwing off a scent of pitch.

Joseph J. Esposito, Ph.D., who is the chief of the C.D.C.'s Poxvirus Section, led me along an outdoor walkway toward his laboratory and office. Esposito is a stocky man of moderate height, in his mid-fifties, who runs to keep his weight down, and he has a dark beard and wears eyeglasses over brown eyes that are perceptive and serious. I asked him if we could get closer to smallpox. We passed along an aerial walkway covered with a chain-link fence, and we turned onto another walkway. We stopped and leaned on a railing. We were facing the C.D.C.'s Level 4 biocontainment building. It contains the Level 4 hot suites-labs where researchers work with lethal viruses while wearing pressurized spacesuits. The building has a line of windows tinted blue-green, like fish tanks. "The variola is in there somewhere," Joe Esposito said, offering me a grave smile and nodding at the Level 4 building. "There is a kind of electricity in the air when we're working with smallpox. Everybody around here always seems to know -- 'Joe's got the smallpox out of the freezer.' "

The smallpox freezer may be encircled by alarms and motion detectors. It may or may not be wrapped in chains. It may be a stainless-steel cylinder. Or it may be a white box intended to look like any other freezer. Officials at the C.D.C. won't comment.

Inside the freezer, the entire collection of smallpox occupies a volume slightly larger than that of a basketball. It consists of approximately four hundred little plastic vials the size of pencil stubs, the residue of D. A. Henderson's war with variola. They're an inch long and they have plastic screw caps. They sit in seven little white cardboard boxes, in a rack inside the freezer, which keeps the virus not strictly alive, not exactly dead, but potent. Most of the vials contain milky ice or bloody ice. The virus has been cultured in flasks of live cells (milky ice) or in live chicken eggs (live eggs have a blood system). Around twenty-five of the vials contain human scabs-dried smallpox pustules. The scabs look like pencil erasers.

The six scabs that were collected from the girl in Bangladesh named Rahima Banu used to sit in a vial, but recently Esposito's group used the last of her scabs for research. The strain that came out of her scabs is known as Bangladesh 1975 -- or, informally, as the Rahima. Now that the scabs are gone, the Rahima exists in vials of milky ice.

Esposito sat hunched in his chair in front of his computer. His office is a windowless room with cinder-block walls. A troll with Shocking-pink hair stood on top of the computer, staring at him wide-eyed. "I like to think like a virus," Esposito said. "If you can think like a virus, then you can begin to understand why a virus does what it does. A smallpox particle gets into a person's body and, in a way, it's thinking, I'm this one particle sitting here surrounded by an angry immune system. I have to multiply fast. Then I have to get out of this host fast. It escapes into the air before the pustules develop." By the time the host feels sick, the virus has already moved on to its next host. The previous host has become a cast-off husk (and is now becoming saturated with virus), but whether the person lives or dies no longer matters to the virus. However, the dried scabs, when they fall off, contain live virus. The scabs are the virus's seeds. They preserve it for a long time, just in case it hasn't managed to reach a host in the air. The scabs give the virus a second chance.

POXVIRUSES move easily through the animal kingdom. Along with herds of animals or swarms of insects come poxviruses circulating among them like pickpockets at a fair. Esposito once classified what he and other virologists have glimpsed of the poxviruses in nature. He noted monkeypox, swinepox, buffalopox, skunkpox, raccoonpox, gerbilpox, a few deerpoxes, a sealpox, turkeypox, canarypox, pigeonpox, starlingpox, peacockpox, dolphinpox, Nile crocodilepox, penguinpox, two kangaroopoxes, and a quokkapox. (The quokka is an Australian wallaby.) Any attempt to get to the bottom of the butterflypoxes, mothpoxes, and beetlepoxes would be something like enumerating the nine billion names of God.

A caterpillar that has caught an insectpox dissolves into a liquefaction of insect guts mixed with pure crystals of poxvirus. This is known as a virus melt. The melt pours out of the dead caterpillar, and other caterpillars come along and accidentally eat the crystals lying on a leaf, and they melt, and so it goes for millions of years in the happy life of an insectpox. "It is a good thing no person has been known to catch an insectpox," Esposito remarked. (You might avoid eating melted caterpillars.) The yellow-fever mosquito, Aedes aegypti, suffers from a fatal mosquitopox. At least two midgepoxes torment midges. Grasshoppers are known to get at least six poxes. If a grasshopperpox breaks out in a swarm of African Locusts, it can wipe them out with a plague.

Viruses have an ability to move from one type of host to another in what is known as a trans-species jump. The virus changes during the course of a jump, adapting to its new host. The trans-species jump is the virus's most important means of long-term survival. Species go extinct; viruses move on. There is something impressive in the trans-species jump of a virus, like an unfurling of wings or a flash of stripes when a predator makes a rush. Some fifty years ago, in central Africa, the AIDS virus apparently moved out of chimpanzees into people. Chimpanzees are now endangered, while the AIDS virus is booming.

For most of human prehistory, people lived in small groups of hunter-gatherers. The poxviruses did not deign to notice Homo sapiens as long as the species consisted of scattered groups; there was no percentage in it for a pox. With the growth of agriculture, the human population of the earth swelled and became more tightly packed. Villages became towns and cities, and people were crowded together in river valleys.

Epidemiologists have done some mathematics on the spread of smallpox, and they find that the virus needs a population of about two hundred thousand people living within a fourteen-day travel time from one another or the virus can't keep its life cycle going, and it dies out. Those conditions didn't occur in history until the appearance of settled agricultural areas and cities. At that point -- roughly seven thousand years ago -- the human species became an accident with a poxvirus waiting to happen.

Smallpox could be described as the first urban virus. It is thought to have made a trans-species jump into humans in one of the early agricultural river valleys -- perhaps in the Nile Valley, or in Mesopotamia, or in the Indus River Valley. In the Cairo Museum, the mummy of the Pharaoh Ramses V, who died as a young man in 1157 B.C., is speckled with yellow blisters from face to scrotum.

In 1991, Joe Esposito and the molecular biologist Craig Venter, who was at the National Institutes of Health, sequenced the entire genome of the Rahima strain of smallpox; that is, they mapped all its DNA. They found that the virus contains a hundred and eighty-six thousand base pairs of DNA (each base pair being a step on the ladder of the molecule), and that the DNA contains about a hundred and eighty-seven genes-making smallpox one of the most complicated viruses known. (The AIDS virus has only ten genes.) A gene is a piece of DNA, which contains the recipe for making one protein. Esposito's team noticed that smallpox has a gene that is also found in the placenta of a mouse. Smallpox knows how to make a mouse protein. How did smallpox learn that? "The poxviruses are promiscuous at capturing genes from their hosts," Esposito said. "It tells you that smallpox was once inside a mouse or some other small rodent." D. A. Henderson speculates that the original host of smallpox may have been an African rodent that lived in a crescent of green forests along the southern Nile River. The forests disappeared, cut down by people, and possibly the rodent has gone extinct. This is only a guess. Smallpox moved on.

THE principal American biodefense laboratory is the United States Army Medical Research Institute of Infectious Diseases, or USAMRIID, in Fort Detrick,

Maryland -- an Army base that nestles against the eastern front of the Appalachian Mountains in the city of Frederick, an hour's drive northwest of Washington. There is no smallpox at USAMRIID, for only the two W.H.O. repositories are allowed to have it. The principal scientific adviser at USAMRIID is Peter Jahrling, a civilian in his fifties with gray-blond hair, PhotoGray glasses, and a craggy face. Jahrling was the primary scientist during the 1989 outbreak of Ebola virus in Reston, Virginia: he discovered and named the Ebola-Reston virus.

"I don't think there is any higher biological threat to this nation than smallpox," Jahrling said to me, in his office, a windowless retreat jammed with paper. His voice was croaking. "I was over in Geneva for a meeting on smallpox, and I came back with some flu strain," he said hoarsely. The flu strain had swept through the world's smallpox experts. "Shows how fast a virus can move. If we have some kind of bioterror emergency with smallpox, there will be no time to start stroking our beards. We'd better have vaccine pre-positioned on pallets and ready to go."

Jahrling opposes the destruction of the official stocks of smallpox. "If you really believe there's a bioterrorist threat out there, then you can't get rid of smallpox," he said. "If smallpox is outlawed, only outlaws will have smallpox." His group has been testing antiviral drugs that might work on smallpox, and he feels that in order to verify the effectiveness of a new drug it would be necessary to test it on live smallpox virus.

One of Jahrling's researchers, John Huggins, led me into the central areas of USAMRIID. Huggins is a chunky man with round Fiorucci eyeglasses. He turned into a corridor leading to the Level 4 spacesuit hot suites, or hot zones. The walls were cinder block, and the light turned bile green. A smoky reek drifted in the corridors, coming from huge autoclaves -- pressure cookers -- where contaminated equipment and waste were being heated and sterilized after being brought out of a hot zone. We stopped at a door that had a window of thick glass, looking into hot suite AA5, the Ebola hot zone.

I pressed my nose against the glass. It was cool, and there was a faint rumble of blowers, keeping the zone at negative pressure, so that no contaminated air would flow out through cracks. The suite was dark and drowned in shadows, illuminated only by light coming from lab equipment. I could see no one in there but white mice in racks of plastic boxes. They were scribble-scrabbling in pine shavings.

"These mice are all infected with Ebola," Huggins said. "They bleed when they die. Like humans."

The mice looked fine. I couldn't see any blood in the shavings.

"We're giving them an antiviral drug that saves their lives," Huggins explained. "They're kind of perky. It's called an S.A.H. drug. It's not ready for human testing. It could work in humans, but we don't know."

In 1995, Huggins spent time in a spacesuit at the C.D.C. Level 4 lab in Atlanta, testing drugs on live smallpox. He found that a drug called cidofovir can block smallpox replication. Cidofovir, which is normally used against a virus that infects AIDS patients, has drawbacks. It must be given to people by I.V. drip, and there is some concern that it might damage the kidneys. Huggins and Jahrling believe that within five years better smallpox drugs are likely to be discovered. They say they will need to test the drugs directly on the virus. They add that the drug must be tested on the live virus in order to receive F.D.A. approval.

In March, a committee of the highly respected Institute of Medicine, in Washington, D.C., concluded that one of the main reasons for retaining live smallpox virus would be to help develop drugs against it. D. A. Henderson, who was not a member of the Institute of Medicine committee and thoroughly disagrees with its conclusions, thought that Jahrling was being too optimistic. "To get a new antiviral drug against smallpox is going to cost three hundred million dollars," he said. "The money simply isn't there."

Jahrling stood his ground. "Ceremonial destruction of smallpox is the crown jewel in D. A. Henderson's career," he said. "He would like to throw the lever on smallpox himself. If I had spent my life tramping the planet to eradicate the virus, I would want to throw the lever, too. What he did was a great accomplishment, but he has become blinded by the last glittering crown jewel of total eradication."

KEN ALIBEK, who was once Kanatjan Alibekov, a leading Soviet bioweaponeer and the inventor of the world's most powerful anthrax, shocked the American intelligence community when he defected, in 1992, and revealed how far the Soviet Union had gone with bioweapons. In a new book of his, entitled "Biohazard," Alibek says that there were twenty tons of liquid smallpox kept on hand at Soviet military bases; it was kept ready for loading on biowarheads on missiles targeted on American cities. I contacted certain government sources and asked them if there was any evidence to corroborate Alibek's claims.

One person who asked not to be named said, "I really have to be careful what I say. Yeah, Alibek's claims have been corroborated in multiple ways. There's not a lot of evidence. There's some."

Another person who asked not to be named said that the Soviet Union had put the biowarheads on ICBM missiles and test launched them sometime before 1991 over the Pacific Ocean. The United States -- probably using spy satellites that orbited near the tests -- was able to monitor the missiles as they soared into space and then punched back through the atmosphere and landed in the sea. The warheads were spinning weirdly: they were unusually heavy, and they had a strange shape. The warhead was heavy because it had an active refrigeration system to keep its temperature near or below the boiling temperature of water during reentry. Nuclear warheads don't need to be actively cooled. Why would a warhead need to be cooled? Presumably, because it was designed to contain something alive. But what? The person said, "The warhead was built to carry a very small quantity of biological weapon. Anthrax wouldn't have worked too well, because you need to put a lot of anthrax in the air to kill people, and anthrax isn't contagious. With smallpox, you don't need much. If you use smallpox, you get around the most difficult technical problem of bioweapons -- the problem of dissemination. With smallpox, you use people as disseminators."

In 1989, a Soviet biologist named Vladimir Pasechnik defected to Britain. British intelligence agents spent a year debriefing him in a safe house. By the end, the British agents felt they had confirmed that the U.S.S.R. had biological missiles aimed at the United States. This information reached President George Bush and the British Prime Minister, Margaret Thatcher. Mrs. Thatcher then apparently telephoned the Soviet leader, Mikhail Gorbachev, and sternly confronted him. She was furious, and so was Bush. Gorbachev responded by allowing a small, secret team of American and British biological-weapons inspectors to tour Soviet biowarfare facilities. In January of 1991, the inspectors travelled across the U.S.S.R., getting whirlwind looks at some of the major clandestine bases of the Soviet biowarfare program, which was called Biopreparat. The inspectors were frightened by what they discovered. ("I would describe it as scary, and I feel a responsibility to tell the world medical community about what I saw, because doctors could face these diseases," an inspector, Frank Malinoski, M.D., Ph.D., said to me.) On January 14th, the team arrived at Vector, the main virology complex, in Siberia, and the next day, after being treated to vodka and piles of caviar, they were shown into a laboratory called Building 6, where one of the inspectors, David Kelly, took a technician aside and asked him what virus they had been working with. The technician said that they had been working with smallpox. Kelly repeated the question three times. Three times, he asked the technician, "You mean you were working with Variola major?" and he emphasized to the technician that his answer was very important. The technician responded emphatically that it was Variola major. Kelly says that his interpreter was the best Russian interpreter the British government has. "There was no ambiguity," Kelly says.

The inspectors were stunned. Vector was not supposed to have any smallpox at all, much less be working with it. All the Russian smallpox stocks were supposed to be kept in one freezer in Moscow, which was supposed to be under the control of the World Health Organization. For Vector to have smallpox would be a supreme violation of rules set down by the W.H.O.

Then they went upstairs into Building 6, and entered a long corridor. On one side was a line of glass windows looking in on a giant airtight steel chamber of a type known as a dynamic aerosol test chamber. The device is for testing bioweapons. Small explosives are detonated inside the chamber, throwing a biological agent into the air of the chamber. The chamber in Building 6 had an octopus-like structure of tubes coming out of it where sensors could be attached or monkeys could be clamped with their faces exposed to the chamber's air. An airborne bioweapon would get into the sensors or into the animals' lungs. On the other side of the corridor was a room that Frank Malinoski said "looked like a NASA control room," and video cameras provided views inside the chamber, so that Vector scientists could watch the release of a bioweapon.

Vector scientists later told the inspectors that the chamber was a Model UKZD-25-a bioweapons explosion-test chamber. It was the largest and most sophisticated modern bioweapons test chamber that has ever been found by inspectors in any country. It was used for testing smallpox.

The inspectors asked to put on spacesuits and to go inside. (They had brought along Q-Tip-like swab kits: they would have liked to swab the inner walls of the chamber, in the hope of collecting a virus.) The Russians refused. "They said our vaccines might not protect us," Malinoski says. "It suggested that they had developed viruses that were resistant to American vaccines." The Russians ordered the inspectors to leave Building 6.

At a large gathering that evening, three inspectors -- David Kelly, Frank Malinoski, and Christopher Davis -- publicly confronted the head of Vector, a virologist named Lev Sandakhchiev, about Vector's smallpox. (His name is pronounced "Sun-dock-chev.") He back-pedalled angrily. Davis, a medical doctor with a Ph.D. who was then with British intelligence, now recalls, "Lev is gnome-like, a short man with a wizened, weather-beaten, lined face, and black hair. He's very bright and capable, a tough individual, full of bonhomie, but he can be very nasty when he is upset." Sandakhchiev heatedly insisted that his technician had misspoken. He called on his deputy, Sergei Netesov, to support him. The two Vector leaders insisted that there had been no work with smallpox at Vector. They had been doing genetic engineering with smallpox genes, they said, but Vector didn't have any live smallpox, only the virus's DNA -- and the more they spoke the murkier their statements seemed. David Kelly remembers, "They were both lying, and it was a very, very tense moment. It seemed like an eternity, but it only lasted about fifteen minutes. And then there were so many other aspects of Vector we had to explore."

"The brazenness of these people!" one inspector later fumed. "They had been testing smallpox in their explosion chamber the week before we arrived."

Lev Sandakhchiev is still the head of Vector. He declined to be interviewed for this account but has steadfastly maintained that no offensive bioweapons research occurs now at Vector. In January of this year, at the Geneva meeting of smallpox experts, Sandakhchiev delivered a paper (and may have caught their flu). In his paper he claimed that Vector did not have any smallpox until 1994, when, he said, Vector had obtained it legally from Moscow. D. A. Henderson was also at that meeting. "It was quite elaborate and quite unbelievable," Henderson said. "I rolled my eyes, and saw other people rolling their eyes at me. We're sitting there, he's presenting us with all this horseshit, and he knows it's horseshit. Sandakhchiev is lying flagrantly."

Four sources have suggested to me that Lev Sandakhchiev was in charge of a Vector research group that in 1990 devised a more efficient way to grow weapons-grade smallpox in industrial-scale pharmaceutical tanks known as bioreactors. The Vector smallpox bioreactors had a capacity of six hundred and thirty litres -- virus tanks big enough for a microbrewery. Once the Vector scientists had worked out the details of variola manufacturing, the results were written up in master production protocols -- recipe books -- and these protocols ended up at the Russian Ministry of Defense, in Moscow. At the time, weapons-grade smallpox was being manufactured by two older methods at a top-secret virus-munitions production plant near the city of Sergiyev Posad, forty-five miles northeast of Moscow. At another virus-munitions plant, near Pokrov, about two hundred miles southeast of Moscow, military virus-production specialists converted the plant to the new Vector method of making smallpox in the large virus bioreactors, but apparently never started the reaction. When one considers that a single person infected with smallpox would be considered a global medical emergency, this is rather a lot of smallpox activity to have bubbling near Moscow. It means that live smallpox virus and the protocols for how to mass-produce it had spread to various places in Russia by the nineteen-nineties. Indeed, live smallpox could be bubbling in reactors now at Sergiyev Posad-no one in the United States government admits to having a clue, and no Russian journalists have seen the place. Peter Jahrling said, "I really think that Vector is out of the offensive BW [biowarfare] business. But Sergiyev Posad is the black hole. We have no contacts there, and the Russians won't allow us to visit the place."

These days, Lev Sandakhchiev has cordial relationships with Peter Jahrling and Joe Esposito. They are eager to draw their colleague into the circle of open international science. During their visits to Siberia, Sandakhchiev has come across to them as warm and human, and desperate for research money to support his institute. Sometimes, candid remarks slip out from the Russians. Jahrling put it this way: "There were tons of smallpox virus made in the Soviet Union. We know that. The Russians have admitted that to us. I was in a room with one of the Vector leaders when he said to us, 'Listen, we didn't account for every ampule of the virus. We had large quantities of it on hand. There were plenty of opportunities for staff members to walk away with an ampule. Although we think we know where our formerly employed scientists are, we can't account for all of them-we don't know where all of them are.' " Today, smallpox and its protocols could be anywhere in the world. A master seed strain of smallpox could be carried in a person's pocket. The seed itself could be a freeze-dried lump of virus the size of a jimmy on an ice-cream cone.

While I was sitting with D. A. Henderson in his house, I mentioned what seemed to me the great and tragic paradox of his life's work. The eradication caused the human species to lose its immunity to smallpox, and that was what made it possible for the Soviets to turn smallpox into a weapon rivalling the hydrogen bomb.

Henderson responded with silence, and then he said, thoughtfully, "I feel very sad about this. The eradication never would have succeeded without the Russians. Viktor Zhdanov started it, and they did so much. They were extremely proud of what they had done. I felt the virus was in good hands with the Russians. I never would have suspected. They made twenty tons -- twenty tons -- of smallpox. For us to have come so far with the disease, and now to have to deal with this human creation, when there are so many other problems in the world . . ." He was quiet again. "It's a great letdown," he said.

For years, the scientific community generally thought that biological weapons weren't effective as weapons, especially because it was thought that they're difficult to disperse in the air. This view persists, and one reason is that biologists know little or nothing about aerosol-particle technology. The silicon-chip industry is full of machines that can spread particles in the air. To learn more, I called a leading epidemiologist and bioterrorism expert, Michael Osterholm, who has been poking around companies and labs where these devices are invented. "I have a device the size of a credit card sitting on my desk," he said. "It makes an invisible mist of particles in the one-to-five-micron size range -- that size hangs in the air for hours, and gets into the lungs. You can run it on a camcorder battery. If you load it with two tablespoons of infectious fluid, it could fill a whole airport terminal with particles." Osterholm speculated that the device could create thousands of smallpox cases in the first wave. He feels that D. A. Henderson's estimate of how fast smallpox could balloon nationally is conservative. "D.A. is looking at Yugoslavia, where the population in 1972 had a lot of protective immunity," he said. "Those immune people are like control

rods in a nuclear reactor. The American population has little immunity, so it's a reactor with no control rods. We could have an uncontrolled smallpox chain reaction." This would be something that terrorism experts refer to as a "soft kill" of the United States of America.

The idea that a biological credit card could execute a soft kill of the United States has reached the White House. The chief terrorism expert on the National Security Council, Richard Clarke, has sent word through the federal government that getting national stockpiles of smallpox vaccine is a top priority.

The effort started four years ago. So far, the government has little to show except numerous meetings among agencies, with no hope of vaccine anytime soon. The Department of Defense has put all its vaccine efforts into something called the Joint Vaccine Acquisition Program, which is run by the Joint Program Office for Biological Defense. People inside the military don't want their names used when they talk about the Pentagon's efforts. "It's a fucking disaster," said one knowledgeable military officer who has had direct experience in the matter. Last year, the Pentagon hired a systems contractor called Dynport, headquartered in Reston, Virginia, to develop and make a number of different vaccines for troops. The smallpox-vaccine contract calls for three hundred thousand doses, at a cost of $22.4 million, or seventy-five dollars a dose, with delivery now scheduled for 2006. (The date has been pushed back at least once already.) This amount of vaccine could be made in about fifteen flasks the size of soda bottles. There are 2.3 million people in the armed forces, and they have several million more dependents. "Three hundred thousand doses is not enough vaccine to protect anyone -- not even our troops. It totally ignores the fact that smallpox is contagious," one military man said. "These guys ought to be buying tank treads and belt buckles. They know nothing about vaccines."

The Department of Health and Human Services (H.H.S.) has been given the responsibility by the White House for producing a stockpile of smallpox vaccine large enough to protect the American civilian population in case of a bioterror event; originally, the idea was for H.H.S. to consider hiring the military's contractor, Dynport, to make forty million extra doses, in addition to the three hundred thousand that Dynport was making for the Pentagon. (Any such initiative would require competitive bidding.)

At a series of meetings at H.H.S., a top Dynport executive said that forty million doses could be quite expensive. One scientist asked if a group of knowledgeable people could be drawn together to come up with an estimate of costs. The Dynport man answered, "Yes, we can do a study that will list the questions that need to be asked. It will cost two hundred and forty thousand dollars and will take six weeks."

Somebody then asked how much it would cost to answer the questions. The Dynport official responded, "That will be a different study. That study will cost two million dollars and will take six months."

With that, one scientist at the meeting burst out, "This is horseshit! We're asking an encyclopedia salesman if we need an encyclopedia!"

The C.E.O. of Dynport, Stephen Prior, said that the situation is more complicated:"The civilian population is very different from the military. There's an age spread from newborns to the elderly, there's more compromised immunity, with AIDS, chemotherapy, and organ transplants. And possibly thirty-five per cent of people have never been vaccinated. So it's not just scaling up the manufacturing."

Another knowledgeable observer is the retired Army General Philip K. Russell, M.D., who gave the order to send biohazard troops into Reston in 1989 to deal with a building full of monkeys infected with Ebola. Russell said to me, "Many of us are afraid that Dynport won't deliver the goods without wasting an inordinate amount of money."

However, H.H.S. has quietly opened talks with other potential contractors, preparing to solicit bids to make a civilian stockpile of smallpox vaccine, though there has been no announcement. "The effort at H.H.S. still isn't organized," D. A. Henderson said. General Russell said, "If smallpox really got going, people should be most concerned about a lack of effective leadership on the part of their government."

I WANTED to get closer to smallpox virus. In Joe Esposito's lab, at the Centers for Disease Control, there was a test going of a biosensor device for detecting smallpox. It was a machine in a black suitcase. It could detect a bioweapon using; the process called the polymerase chain reaction, or P.C.R. -- the same kind of molecular fingerprinting that police use to identify the DNA of a crime suspect. The suitcase thing was called a Cepheid Briefcase Smart Cycler, and it had been co-invented by M. Allen Northrup, a biomedical engineer who founded a company to make and sell biosensors. He was there, along with a cluster of other scientists.

Esposito, the official guardian of one half of the world's official supply of smallpox, handed a box of tubes to a scientist in the room. Two of the tubes contained the whole DNA of smallpox virus but not live smallpox. The DNA drifted in a drop of water; it was the Rahima strain. Two other tubes contained anthrax. The samples were snapped into slots in the machine.

Northrup turned his attention to a laptop computer that nestled in the machine. Northrup is a chunky man with a mustache and reddish-brown hair. He tapped on the keys.

We waited around, chatting. Meanwhile, the Cepheid was working silently. It showed colored lines on its screen. In fifteen minutes, the anthrax lines started going straight up, and someone said, "The anthrax is screaming." Finally, one of the smallpox lines crept upward, slowly. "That's a positive for smallpox, not so bad," a scientist said. Emergency-response teams could carry a Cepheid suitcase to the scene of a bioterror event and begin testing people immediately for anthrax or smallpox. The machine is priced at sixty thousand dollars.

Afterward, Joe Esposito went around collecting the used tubes. The smallpox-sample holder -- a plastic thing the size of a thumbnail-had been left on a counter. I picked it up.

Esposito wasn't about to let anyone walk off with smallpox. "Leave me that tube," he said. "You are not allowed to have more than twenty per cent of the DNA."

Before I handed it to him, I glanced at a little window in the tube. When I held it up to the light, the liquid looked like clear water. The water contained the whole molecules of life from variola, a parasite that had colonized us thousands of years ago. We had almost freed ourselves of it, but we found we had developed a strong affinity for smallpox. Some of us had made it into a weapon, and now we couldn't get rid of it. I wondered if we ever would, for the story of our entanglement with smallpox is not yet ended.

1999 (October 11) - The New Yorker, October 18 & 25, 1999, pp.90-107 - "West Nile Mystery" by RICHARD PRESTON

"WEST NILE MYSTERY : How did it get here? The C.I.A. would like to know."

http://cryptome.org/west-nile.htm / 1999-10-18-cryptome-org-new-yorker-west-nile-mystery.pdf / https://drive.google.com/file/d/1wFZnPQKnCmeleaFCoaxVLDomXkBrFyOO/view?usp=sharing

Last spring, long before the outbreak, an Iraqi defector declared Saddam Hussein had told him of plans to use the virus as a bioweapon.

_____

SINCE the end of August, a brain virus that is now believed to be a previously unknown variant of the West Nile virus has killed at least five people around New York City and its suburbs. This has created a stir in the national news media -- and a whiff of concern within the C.I.A. that the outbreak might have been an act of bioterrorism -- but the main effect of the outbreak in humans has been quiet: thousands of New Yorkers may have had West Nile virus replicating in their brains this summer without knowing it. In most people, the West Nile illness feels like a mild flu. Humans catch it from the bite of an infected mosquito. You might get a headache and a backache and the blahs; just another summer bug. Usually, the illness lasts from three to six days, and people recover quickly, without lasting effects. But in young children, the elderly, and people with weak immune systems West Nile can turn into encephalitis -- an inflammation of the brain. The brain becomes red and puffs up inside the skull. These victims may get tremors -- their muscles may become uncontrollably weak -- and they can have seizures, fall into a coma, stop breathing, and die.

The West Nile virus was first identified by virologists in 1937, in the West Nile district of Uganda, along the Albert Nile near the border with the Congo, where it was making people sick. West Nile virus is a traveller. Mosquitoes are its main carriers and birds are its main hosts; they are its deep reservoir in nature. It has been found all over east Africa, in western India, in Australia (where one of its close relations is known as Kunjin), and in Egypt and the Middle East. About forty per cent of the people who live in the Nile Delta in Egypt have been infected with West Nile at some point in their lives. Although the virus stages occasional outbreaks in people, the real outbreaks are happening in birds, and people are bystanders caught in the crossfire -- bitten by chance by an infected mosquito. The virus also gets into ticks. From the point of view of the West Nile virus, the human species is of less consequence than a tick. In a manner of speaking, West Nile doesn't even know we exist. But when West Nile moves with the birds there is splatter damage among humans. Birds occasionally carry West Nile into Eastern Europe during their annual migrations out of Africa. Right now, there is a major outbreak of what is believed to be the West Nile virus in southern Russia, around the cities of Volgograd and Rostov-on-Don. There are reports that some six hundred people have been taken ill, and at least thirty-two have died. American scientists have been trying to persuade Russian scientists to send them samples of tissue and blood from the Russian outbreak, so that they can compare the New York strain with the Russian strain. It might show that the New York strain somehow came from Russia, perhaps travelling by airplane in the bloodstream of an infected Russian who ended up in Queens and was bitten by a mosquito there, and the mosquito then passed it to a bird. So far, the Russians haven't sent any samples.

Until this summer, the West Nile virus had never been seen in the Western Hemisphere. Some virus experts think that the leap of West Nile virus into North America -- if this is indeed what has happened -- is one of the most important biological events to occur in the world of the viruses in this century. For one thing, until now the virus has generally not been fatal to its avian hosts. For another, the outbreak reveals the mobility of viruses and their propensity to cross continents. The experts have no idea how the virus got to New York and little idea where it's going. Possibly, an infected bird somehow flew across the ocean -- or hitched a ride on a ship, or was imported legally or illegally. Or perhaps an infected mosquito got here on a plane. The virus may now be headed down the eastern seaboard of the United States for the winter, travelling inside birds. In late June or early July, the virus apparently showed up in birds in the Whitestone area of northern Queens and in the South Bronx. The birds caught it from an urban mosquito, Culex pipiens -- Latin for "chirping bug" -- commonly known as the house mosquito. This mosquito breeds all over the world in polluted water. Where the mosquitoes of New York City got the West Nile virus is unknown.

IN mid-August, Dr. Tracey McNamara, a veterinary pathologist with the Wildlife Conservation Society, at the Bronx Zoo, began hearing reports of dead birds all around New York City. Then she noticed dozens of dead and sick crows around the zoo. "I'm sitting there saying, 'It's raining crows,' " she recalls. "The sick ones were neurologic -- they couldn't fly, they had trouble balancing. They were sitting there with tremors." Dr. McNamara performed necropsies, and when she opened the birds' skulls she found that they'd had brain hemorrhages; she also found lesions on their hearts. Then, the day after Labor Day, there was a big die-off of birds at the zoo. A number of South American flamingos and cormorants died, and a bald eagle developed head tremors and died. Dr. McNamara sensed that an unknown virus was killing the birds. She already suspected it was being passed by mosquitoes, and she feared that it could be lethal to humans. She began taking extra precautions: she handled the birds only with special equipment, and opened them up in a filtered-air safety cabinet. She notified health authorities and sent them samples for analysis.

At roughly the same time, Dr. Deborah Asnis, at the Flushing Hospital Medical Center, in Queens, was treating two elderly patients who were dying of an apparent encephalitis virus, but she couldn't diagnose it. Dr. Asnis brought it to the attention of doctors at the New York City Department of Health, who sent samples of human brain tissue to a laboratory of the federal Centers for Disease Control and Prevention in Fort Collins, Colorado, where Dr. Duane Gubler, the director of the Division of Vector-Borne Infectious Diseases, made a tentative identification of St. Louis encephalitis virus. That virus lives in birds and mosquitoes in the South and Midwest, and had never been seen in New York On Friday, September 3rd, city officials learned that the C.D.C. believed that the virus was St. Louis encephalitis, and just two hours later Mayor Rudolph Giuliani ordered trucks and a helicopter to begin spraying insecticides over neighborhoods in northern Queens. The spraying eventually involved five helicopters, and was carried out all over the city and in many suburbs. The chief of the Mayor's Office of Emergency Management, Jerome Hauer, bought half a million cans and bottles of Off! and other insect repellents on behalf of New York City. He ended up cornering nearly the entire supply of insect repellent in the United States. The city handed out the bug repellent for free. Hauer also is in charge of New York City's preparations for a bioterror event. A bioterror event is the deliberate release of a biological weapon, such as anthrax or smallpox, by a terrorist a possibility that has city officials very concerned, and they've been having planning sessions and staging simulated terror exercises. It may be that their preparations for a bioterror event fortuitously speeded up the city's response to the outbreak of the brain virus.

Then two groups of scientists almost simultaneously discovered that the virus wasn't St. Louis encephalitis virus but West Nile -- or something close to West Nile. One group was led by Dr. Ian Lipkin, of the Emerging Diseases Laboratory at the University of California at Irvine, who was studying bits of brain tissue from people who had died in New York. The other group was led by Duane Gubler, of the C.D.C. lab in Colorado. Both Lipkin and Gubler were

attempting to decode the DNA of the virus to determine exactly what the virus is. It might be given a new name, Lipkin told me early last week: "We could call it the Hudson River virus. We won't call it the Queens virus. People don't like to have viruses named after the places they live." Then, at the end of the week, Lipkin announced that he believed the virus was indeed a new strain, and that it is most closely related to the West Nile virus and its relative the Australian Kunjin virus.

THE mystery of how a West Nile-like virus got to New York City has been troubling the Central Intelligence Agency. At the headquarters of the C.I.A., in Langley, Virginia, there is a group of analysts and officers who concern themselves with biological weapons -- the C.I.A.'s bioweapons-analysis section. The section is run by a senior biologist who has had firsthand experience with some of the world's most dangerous viruses, including the Ebola virus. The scientist is said to be well respected by his peers, and he works with a team of analysts, mainly younger people fresh out of college. The analysts gather intelligence involving bioweapons and then try to assemble the big picture, fitting the data together with what they already know about bioweapons. After the New York diagnosis was changed to West Nile, on September 27th, the top officers in the bioweapons-analysis section suffered a lurch of uneasy recognition: they recalled a report that a self-described defector from Iraq had declared last April that Saddam Hussein was developing a strain of the West Nile virus as a biological weapon and was preparing to release it.

Someone in the analysis section apparently noticed that on April 6th a British tabloid, the Daily Mail of London, had published an excerpt from a book entitled "In the Shadow of Saddam," with a note that the account's credibility was "for the reader to judge." The author calls himself Mikhael Ramadan. That may or may not be his real name. Mikhael Ramadan is said to look a lot like Saddam Hussein. Purportedly, he served as one of Saddam's doubles, in order to help foil assassination attempts. There is a photograph, supposedly of him, on the back cover of the book, and he looks remarkably like Saddam except that he has more gray at the temples, and somehow he looks kindly. Eventually, Mikhael Ramadan managed to escape from Iraq. In his book he offers a wild-sounding account of his experiences working as Saddam's double, including such vignettes as a Kurdish rebel being lowered slowly into a vat of sulfuric acid. Mr. Ramadan also wrote, as the Daily Mail published it:

In 1997, on almost the last occasion we met, Saddam summoned me to his study. Seldom had I seen him so elated. Unlocking the top right-hand drawer of his desk, he produced a bulky, leather-bound dossier and read extracts from it.... The dossier holds details of his ultimate weapon, developed in secret laboratories outside Iraq.... Free of UN inspection, the laboratories would develop the SV1417 strain of the West Nile virus-capable of destroying 97 pc [per cent] of all life in an urban environment.... He said SV1417 was to be "operationally tested" on a Third World population centre.... The target had been selected, Saddam said, "but that is not for your innocent ears."

It sounded crazy. But why would a man presenting himself as an Iraqi defector predict that Saddam would unleash a virus just months before the same one broke out unexpectedly in New York? And, of all the thousands of viruses in the world, why West Nile? It was enough to make any bioweapons analyst at the C.I.A. feel uneasy. Adding another twist to the story, it turns out that in 1985 the Centers for Disease Control had sent samples of West Nile virus to a researcher in Iraq, which occasioned a controversy in the media five years later, on the eve of the Gulf War, when reports came out that Iraq had a biowarfare program. But the fatality rate for West Nile is not remotely near ninety-seven per cent, and "SV1417" is not a standard designation for any known strain of West Nile virus. It may be a code designation for some strain that Saddam's bioweaponeers might conceivably be working on, perhaps in a French-built virology facility near Baghdad that has been closed to inspectors from the United Nations for two years, ever since Saddam threw out all the U.N. inspectors. In the early nineteen-eighties, a French vaccine company, Institut Merieux, which is a division of the pharmaceutical giant Rhone-Poulenc, built a facility called the Foot and Mouth Vaccine Plant at a site now known as Al Manal. Institut Merieux helped the Iraqis operate Al Manal for a time, and trained the staff before departing. Al Manal was subsequently used for research into virus weapons. During the Gulf War, Al Manal and the Merieux equipment were used for making twenty thousand litres of botulinum toxin, or BTX -- one of the most lethal biotoxins known. In 1992, the United Nations tore down the buildings in which the BTX was made and destroyed that equipment, but it left standing eighty per cent of the facility, part of which was for virus research. (Some inspectors wanted the whole thing torn down.) Al Manal may be back in business developing virus weapons.

At the same time that the report about West Nile virus was being discussed in the C.I.A., Dr. Ken Alibek, the former deputy chief of research for Biopreparat, the Soviet Union's main biowarfare program -- he defected to the United States in 1992 -- spoke to various people on Capitol Hill, voicing his concern that the West Nile outbreak was suspicious. "I told them, 'It will not be possible to say whether or not it is terrorism unless we have a thorough study,' " he explained to me. "We need to take these situations with a high degree of seriousness."

Mikhael Ramadan is now apparently in hiding somewhere in Canada or the United States. At any rate, the C.I.A. people had an interest in finding him. Presumably, they would want to ask him more questions about the West Nile virus and whatever Saddam might have told him about any plans Iraq might have had for it and New York City. I don't know whether they succeeded in finding him.

Hoping to speak with Mikhael Ramadan myself, I called his publisher, a tiny outfit called GreeNZone Publishing, which has an office in the south of England. One of the firm's three directors, James Bartholomew, answered the telephone. "We don't know Mikhael Ramadan's whereabouts," he said. "We believe he was in Canada for a while. We have five employees here, and none of our people has ever met him. We were introduced to him through a third party. There was a woman, an American-Iraqi nurse, involved in bringing him forward. There was a verification meeting with him that took place in the fall of last year, in Canada, I guess. All of our communication with him has been by E-mail. His E-mail address is now defunct. His manuscript was physically delivered to us by a courier outfit. We tried to get him to change his mind and come forward for television interviews. We had inquiries from NBC and CBS. What is that show, '60 Minutes'? -- they were trying to find him. The book has sold well for a company our size. We want to pay him, but we can't find him."

"Is the book fiction?"

"We've taken his book as true, based on the evidence we have. But we don't know how much of it is true."

"What's the evidence?"

"I can't say. It would put him in danger," Mr. Bartholomew said. "True or not, it was a good story. We saw it as a commercial proposition. We weren't trying to educate the world."

I THEN spoke with the Secretary of the Navy, Richard Danzig. As early as 1993, Danzig had played a leading role in encouraging the government to plan for a possible bioterror event. He is a soft-spoken man with a thin face and spectacles, and he didn't sound alarmed. "A point I've been making to emergency planning groups is that, though we may know that a biological event has occurred, we may not know if it's an incident of bioterrorism," he said. "Even if you suspect biological terrorism, it's hard to prove. It's equally hard to disprove. This is more illuminating of my prediction that we won't necessarily know when bioterror has occurred than it is illuminating of Saddam Hussein."

I called a top scientist who advises the F.B.I., a person who has been deeply involved with bioterror planning. The F.B.I. is currently investigating more than two hundred threats, hoaxes, and attempts at bioterrorism that have occurred in the United States in just the past year -- it's got to the point where every

two hundred threats, hoaxes, and attempts at bioterrorism that have occurred in the United States in just the past year -- it's got to the point where every wanna-be terrorist is threatening to unleash a bug. This scientist seemed thoughtful, and said that West Nile might be a good one. He said, "If I was planning a bioterror event, I'd do things with subtle finesse, to make it look like a natural outbreak. That would delay the response and lock up the decisionmaking process."

An Army expert on bioweapons told me that the military has known for some time that Soviet biologists working for the U.S.S.R.'s biowarfare program had evaluated the West Nile virus for use as a biological weapon. "The Russians did this kind of crap back in the seventies -- they're admitting it to us now," he said. The Soviet scientists were interested in West Nile because it can be put into mosquitoes and the mosquitoes can be released into a city, where they will bite people. "They abandoned it because it didn't work very well," he said. "How many containers of West Nile-infested insects do you need to release in Queens to make it worth a shot?"

BY Friday, October 1st, the Mikhael Ramadan story had surfaced at the Centers for Disease Control, in Atlanta. Dr. Scott Lillibridge, who is the head of the C.D.C.'s Bioterrorism Preparedness and Response Program, alerted other scientists at the C.D.C. about the allegations and asked them to evaluate the evidence. I spoke with a person at the C.D.C., who said, "We're taking it seriously. We'll see where the data takes us. It could be done. You'd have to bring in a lot of mosquitoes." If the mosquito-filled containers were made of plastic, they would not show up in a metal detector at Kennedy International Airport. He went on, "But West Nile is not a great biological weapon, because it doesn't hurt most people very much."

An expert on insect viruses named Dr. Thomas Monath, who ran the C.D.C.'s Fort Collins lab, and later worked for the Army, and is now the chief scientist at a Massachusetts biotech firm called OraVax, took a longer perspective. He thought that the appearance of West Nile in North America was one of the most exciting things that he'd ever seen in his life. "My favorite hypothesis, at the moment, is that a human accidentally brought it here," he said. He thought it was quite possible for a single infected person to have passed through Kennedy International Airport, gone into Queens, and been bitten by a house mosquito, which in turn gave it to a bird. "Unlike most of its relatives, West Nile produces a lot of virus particles in the human bloodstream," Dr. Monath said. "Some people can develop about three thousand to ten thousand particles of the virus in every millilitre of their blood." A millilitre is roughly a quarter of an eyedropper. The particles of West Nile look like golf balls when photographed in an electron microscope. A Culex pipiens mosquito could suck multitudinous golf balls of West Nile into its gut while feeding on human blood.

"West Nile already knows Culex pipiens well, because that mosquito lives all over the world," Monath said. "But now the virus is encountering a whole new ecosystem in North America. Everything else will be unfamiliar to the virus -- the weather and climate, the ticks, many of the birds -- so it's got a job ahead of it in order to become established. Winter is coming on. In order to maintain itself and reproduce, it's got to find a suitable ecosystem. And it's got to find a mechanism for surviving the winter. Humans are just getting in the way. They have nothing to do with its survival. In Africa, it migrates with the birds. Right now, the birds of eastern North America are heading south for Florida and the Caribbean, and they will be going as far as Brazil and Argentina. We could see an outbreak of West Nile in Buenos Aires. It could also persist locally in the New York area, in hibernating mosquitoes. The virus may not be successful at overwintering, but if it is it will take us years to understand the impact and spread of West Nile in the New World."

On Wednesday, October 7th, a man in his twenties from Lakewood, New Jersey, reportedly became the first suspected case of West Nile-like encephalitis south of New York City. Last week, he was in critical condition. New Jersey health officials reported that they had picked up fifty dead crows around New Jersey; fifteen of them have tested positive for the virus. Tracey McNamara, at the Bronx Zoo, said, "I'm certain that the number of birds being reported dead is a gross understatement." A woman in Hopewell, New Jersey, found five dead blue jays and crows, but threw them away before health officials could pick them up.

AT sunrise a couple of days ago, I went up on a ridge overlooking the Hopewell Valley, near where I live. I walked to the top of a field. Trees stood in field lines all around. Birds were chirping, and I heard the squawking of a grackle. The trees were smoky and tinged with yellow. Cloud decks were moving in, and the sun had not yet risen. A fingernail of moon shone through breaks in the running clouds, and I picked out the morning star, Venus, a pinpoint of light near the moon. The sun rose, and Venus was washed away in the head of dawn. The birds started lifting off, and all were flying from north to south, except for two crows, who loitered in an ash tree at the bottom of the field like hoods on a corner, flapping around and looking for crow-excitement.

Three flycatchers wove for insects, weaving always southward. Two more flycatchers came by, going south, and three finches passed, going south, and a lone bird with sharp wings beat by, going south, and then three grackles humped along, keeping the rising sun on their leftward wings. Milkweed in the field was dying, its leaves turning brown at the edges. I broke open a milkweed pod, and two shockingly red beetles tumbled into my fingers. They'd been feeding on the milkweed and probably laying eggs. I tore out the milkweed seeds and threw them in the air. A few parachutes of milkweed deployed, and the seeds drifted across the field. Everything alive understood what was coming. What was coming, for many organisms, was death. For them, death was not what we think of as death but a means of survival. You die on purpose, to give your genes their best chance to spread out into the world and remain alive. This valley in New Jersey reminded me in a strange way of Kitum Cave, on Mt. Elgon, in East Africa, a haunting place I'd seen some years ago. Kitum Cave is suspected of harboring a type of the Ebola virus called Marburg, which is thought to carry on its life cycle inside some unknown animal that visits the cave or lives there. The natural host of the Ebola virus has never been identified. The cave in Africa and the field in New Jersey were two habitats bursting with life, and in them were viruses, active but unseen, carrying on their life cycles. I could not see Ebola in Kitum Cave any more than I could see West Nile pouring through the Hopewell Valley. However this biological event began, it has become something important in nature. In discovering the New World, West Nile has killed a few humans and managed to roil the C.I.A., but now it has more important business -- to find a way, somehow, to keep making copies of itself. If the virus continues migrating south with the birds, and if it finds a place to hide this winter, the only way we will know is if it comes back next year.

Life and early career[edit]

Preston was born in Cambridge, Massachusetts and grew up in Wellesley, Massachusetts. A graduate of the Cambridge School of Weston in Weston, Massachusetts, and Pomona College in Claremont, California, Preston began his writing career at the American Museum of Natural History in New York.

From 1978 to 1985, Preston worked for the American Museum of Natural History as a writer, editor, and manager of publications. He served as managing editor for the journal *Curator* and was a columnist for *Natural History*magazine.[1] In 1985 he published a history of the museum, *Dinosaurs In The Attic: An Excursion into the American Museum of Natural History*, which chronicled the explorers and expeditions of the museum's early days. The editor of that book at St. Martin's Press was his future writing partner, Lincoln Child.[2] They soon collaborated on a thriller set in the museum titled *Relic*. It was subsequently made into a motion picture by Paramount Picturesstarring Penelope Ann Miller, Tom Sizemore, and Linda Hunt.

In 1986, Preston moved to New Mexico and began to write full-time. Seeking an understanding of the first moment of contact between Europeans and Native Americans in America, he retraced on horseback Francisco Vásquez de Coronado's violent and unsuccessful search for the legendary Seven Cities of Gold. That thousand mile journey across the American Southwest resulted in the book *Cities of Gold: A Journey Across the American Southwest*. Since that time, Preston has undertaken many long horseback journeys retracing historic or prehistoric trails, for which he was inducted into the Long Riders' Guild.[3] He has also participated in expeditions in other parts of the world, including a journey deep into Khmer Rouge-held territory in the Cambodian jungle with a small army of soldiers, to become the first Westerner to visit a lost Angkor temple. He was the first person in 3,000 years to enter an ancient Egyptian burial chamber in a tomb known as KV5 in the Valley of the Kings.[4] Preston participated in an expedition that led to the discovery of an ancient city in an unexplored **valley in the Mosquitia mountains of Eastern Honduras,** which he chronicled in a nonfiction book, *The Lost City of the Monkey God: A True Story*.[5] O**n that expedition he and other expedition members contracted an incurable tropical disease known as mucocutaneous leishmaniasis, for which he received treatment at the National Institutes of Health. In 1989 and 1990 he taught nonfiction writing at Princeton University. He has been active in the International Thriller Writers organization.[6]**

U.S. CENTERS FOR DISEASE CONTROL, VIA AP

An image of the Ebola virus, which has killed more than 5,000 people in West Africa.

B.C. network to adapt response to Ebola crisis

RANDY SHORE
Vancouver Sun

VANCOUVER — Infectious-disease researchers at the University of B.C. are establishing a support network for researchers and field workers battling the Ebola outbreak in West Africa.

"We have a number of experts here at UBC who are involved with the international response to Ebola, but [also] a lot of other scientists who have expertise who are looking to be involved," said Rich Lester, director of the university's Neglected Global Diseases Initiative.

The UBC/B.C. Ebola Action Network is an opportunity to take an inventory of local expertise and existing research projects, and to advocate for research funds while forging links among experts.

Researchers and medical staff going into infection zones need to make contact with established experts in safety protocols and connect them with partner organizations already on the ground.

"Simply knowing who else is going and who has been in-country is a great opportunity to exchange information. And we hope that helps us facilitate people to get involved overseas," Lester said.

Government and philanthropic funding sources are being sought to create a fund for new projects based in B.C., he said. The Neglected Global Diseases Initiative was founded to direct energy toward diseases that suffer from a lack of research attention.

"These diseases can have an enormous impact on the communities that they affect, and Ebola as an emerging disease fits into that category," Lester said. "UBC and the NGDI have been world leaders in making new treatments accessible and affordable in resource-limited settings where they are needed."

The first step toward bringing all the available expertise together is this week's symposium on Ebola treatment and action at UBC's Vancouver campus. Keynote speakers include scientists leading the world's efforts to control the disease such as Ian MacLachlan, chief technical officer of Burnaby-based Tekmira Pharmaceuticals, and Xiangguo Qiu, head of the serology diagnostics unit at the Public Health Agency of Canada's National Microbiology Laboratories.

Meanwhile, in Washington, a top U.S. official outlined plans Wednesday for clinical trials of a possible Ebola vaccine in West Africa, as the global response to the outbreak took on added urgency with the disclosure of a new cluster of cases in Mali and reports that the death toll had surpassed 5,000.

Two studies of a U.S.-developed vaccine will begin in Liberia and Sierra Leone by January and if they go well, "we could know by the middle of 2015 whether or not we have an effective vaccine," Dr. Anthony Fauci, infectious disease chief at the National Institutes of Health, told the Senate Appropriations Committee.

December 12, 2014 - Neglected Global Diseases Initiative - NGDI Ebola Symposium for Treatment and Action

PDF (Program) - [HI000L][GDrive]

"On November 13, 2014 UBC's Neglected Global Diseases Initiative at UBC (NGDI-UBC) in partnership with the Vancouver Coastal Health Research Institute and The Centre for Drug Research and Development (CDRD), Canada's national not-for-profit drug development and commercialization centre, brought together leading researchers from across the country to discuss Ebola Treatment and Action. The meeting focused on Canada's current contributions to potential therapeutics in response to the 2014 West African outbreak of Ebola Virus Disease (EVD) and the opinions of Canadian Public Health officials and researchers for the prevention, and control of infection domestically."

Keynote Speaker Biographies - Xiangguo Qiu, MD MSc :

*"**Dr. Xiangguo Qiu** received her M.D. degree in 1985 at Hebei Medical University and M.Sc. in immunology in 1990 at Tianjin Medical University. She went to MD Ander-son Cancer Center (USA) as a visi□ng Scien□st in 1996 and moved to Cancer Care Manitoba (Canada) in 1997 as a research associate. In 2003, she joined the Special Pathogens Program at the Na□onal Microbiology Laboratory at the Public Health Agency of Canada to start studying the most deadly viruses, such as Ebola/ Marburg/Lassa, in the only level 4 (highest containment level) laboratory in Cana-da. Her primary field is immunology with research emphasis on vaccine develop-ment, post-exposure therapeu□cs and rapid diagnos□c of haemorrhagic viruses. As a member of WHO expert team, she and her colleagues provided advises/technical support for biosafety in 2008 Beijing Olympics, 2010 Shanghai Expo, 2010 Asian games in Guangzhou, 2010 winter Olympics in Vancouver and G8/G20 in Toronto, Canada. Her group has first demonstrated that mAbs completely protect nonhu-man primates from Ebola virus infec□on in the filovirus field. Moreover, she and colleagues have developed ZMapp which has been compassionately used in several Ebola infected pa□ents and showed very promising outcomes. Currently, Dr. Qiu heads Serology Diagnos□cs Unit in Special Pathogens Program of Na□onal Microbi-ology Laboratory, Public Health Agency of Canada."*

2014 (November 20) - Canadian Researchers Come Together to Combat the Ebola Outbreak (Vancouver, British Columbia, Canada)

See [HI000N][GDrive]

[HI000O][GDrive]

Last week, UBC's Neglected Global Diseases Initiative at UBC (NGDI-UBC) in partnership with the Vancouver Coastal Health Research Institute and The Centre for Drug Research and Development (CDRD), Canada's national not-for-profit drug development and commercialization centre, brought together leading researchers from across the country to discuss Ebola Treatment and Action. The meeting focused on Canada's current contributions to potential therapeutics in response to the 2014 West African outbreak of Ebola Virus Disease (EVD) and the opinions of Canadian Public Health officials and researchers for the prevention, and control of infection domestically.

NGDI logo2Dr. Richard Lester, Director of NGDI-UBC and Assistant Professor in Infectious Diseases and Global Health in the Department of Medicine states, "In this time of a health crisis in West Africa, we were really privileged to hear the scientific stories behind the development of these hopeful treatments for Ebola. There is still urgent work to be done on this crisis, and these Canadian scientists and practitioners are inspiring examples of how local expertise can contribute in the global context. We hope to encourage even more contributions, like those from CDRD, to close the gap in access to expert care and medicines for the world's most vulnerable, remote, or underserved populations."

NGDI-UBC is currently working closely with CDRD to identify how best to use the extensive capabilities of its biologics platform to employ a novel approach to developing the next generation of therapeutic monoclonal antibodies for the prevention and treatment of Ebola; bringing its industry partners, and combined 40-plus years of therapeutic antibody development experience in rapidly developing candidate antibodies with enhanced effector functions to the table.

CDRD newCDRD President and CEO, Karimah Es Sabar commented, "This timely symposium has focused the mindset of an expert panel of immunologists, public health clinicians, officials and drug developers to work collaboratively through NGDI to accelerate the development of safe, efficacious and affordable treatments for Ebola. It is a neglected disease which affects the most vulnerable people in the poorest communities on this planet. CDRD is committed to working with UBC's NGDI, and leveraging our vast network of industry and academic collaborators to determine how we can best contribute to developing the next generation of biologics treatments for this devastating disease."

Dr. Bonnie Henry, Deputy Provincial Health Officer, BC Ministry of Health and Associate Professor, School of Population and Public Health, Faculty of Medicine UBC opened the symposium with a detailed overview of the symptoms, transmission and mortality of EVD. To-date, 14,000 people have been infected with Ebola in the current outbreak which came to light in March 2014, but is thought to have originated in late 2013. From a public health perspective, Canada is well prepared to deal with patients who may present with symptoms and subsequently test positive for EVD. A Special Advisory Committee is in place, consisting of Public Health Experts from across the nation in addition to a BC Provincial Task Force on-hand to advise best practices if and when suspected cases arise.

From a treatment perspective, there are three Canadian contributions that are being fast-tracked through clinical trials but the challenge remains to find companies and researchers willing to translate their EVD research from bench to bedside. **The keynote speakers focused on two of these contributions; the National Microbiology Laboratory's therapeutic monoclonal antibody, ZMapp and Tekmira Pharmaceutical's TKM-Ebola lipid nanoparticle (LNP) therapeutic. Dr. Xiangguo Qiu of the National Microbiology Laboratory (NML), Public Health Agency of Canada said that the challenges associated with controlling the spread of the current outbreak are multi-factorial. Firstly, this outbreak occurred outside the traditional "hotspot" of Eastern Africa and therefore, local communities were poorly prepared for this event. This lack of preparedness and understanding has culminated in community resistance to foreign health workers and a local underestimation of the problem. Additionally, there is increased travel by West Africans and a greater number of inexperienced medical staff combating this outbreak.**

Ebola Audience 2The NML is responding in a three-pronged approach; they have set up a mobile diagnostic lab which has been based in Sierra Leone since June 2014; they have produced a vaccine with the vesicular stomatitis virus (VSV) vector and they have developed a monoclonal antibody (mAb) therapeutic. The VSV vaccine induces strong B- and T-cell responses. This vaccine has been tested as a post-exposure therapeutic and has been shown to provide 100% protection 28 days post-immunization. This vaccine is currently in Phase I trials and 1,000 doses have been donated for use in the current outbreak. Over the past 10 years, the NML has also been developing a mAb which targets Ebola virus glycoprotein (EBOV GP 1.2). This is the primary protein involved in the pathogenesis of EVD. It is produced using a hybridoma model followed by humanization of purified mAbs. ZMAb is a cocktail of these mAbs which was observed to be 100% efficacious in a study using rhesus monkeys. ZMapp; the chimeric combination of ZMAb also showed very high survival rates in in vivo models. Both have been used in the treatment of 9 Ebola patients during the current outbreak. Five out of 7 patients treated with ZMapp survived while both patients treated with ZMAb survived.

Dr. Ian MacLachlan, Executive Vice President and Chief Technical Officer of Vancouver-based Tekmira Pharmaceuticals spoke about their siRNA-based LNP therapeutic targeting the Kikwit strain of Ebola. These LNP formulations are highly uniform and highly stable. The siRNA targets V24, VP35 and LPol genes on the Ebola virus. The lyophilized formulation has shown increased potency and increased therapeutic index and appears to ameliorate pathology due to EVD such as coagulopathy. The Tekmira product has been used to treat an undisclosed number of patients in the current outbreak. There is ongoing development of this product to account for mismatched sequences between LPol and VP35 in the current strain. However, the LNP platform has allowed Tekmira to rapidly adjust the product configuration in response to the emergent virus.

By bringing Canada's vast health research resources to bear, we as a nation are already making a major global impact on this devastating disease, and by further fostering dialogue and collaboration, and sharing knowledge and resources, we now aim to amplify both our national efforts and impact

Doctors up for awards

WINNIPEG scientists who have developed an antibody-based treatment to treat Ebola, called ZMapp, are among the Manitoba nominees for the Manning Innovation Awards.

Dr. Gary Kobinger, head of special pathogens at Canada's National Microbiology Laboratory, and Canadian Public Health Agency biologist Dr. Xiangguo Qiu join fellow Manitobans Dr. Mark Torchia and Richard Tycm, co-founders of Monteris Medical Inc., as contenders for the $100,000 award.

Monteris has developed technology to destroy brain tumours

The ZMapp is the first experimental Ebola drug used in an outbreak. It's considered the most promising of experimental treatments.

The technology behind Monteris Medical originated from the St. Boniface General Hospital Research Centre. Called the NeuroBlate System, it enables MRI-guided vaporization of deep-seated brain tumours using minimally invasive entry into the target area.

THE END OF EBOLA?

Vaccine co-creator sets his scientific sights on other deadly,

By Martin Cash

FOR much of April, Gary Kobinger lazily sailed a boat up the Big-tombee/Tennessee rivers from his wife's hometown of Mobile, Ala.

It was the first break Kobinger has had for some time, especially since the massive outbreak of Ebola in West Africa in early 2014.

Kobinger, 46, is the chief of special pathogens at Canada's National Microbiology Laboratory on Arlington Street in Winnipeg.

Since he was a post-doctoral scientist at the University of Pennsylvania in 2002 making regular trips to the lab in Winnipeg, he has been researching the Ebola virus.

He became a full-time employee at the lab in 2005.

Kobinger and Dr. Xiangguo Qiu, a Canadian Public Health Agency biologist at the lab, were recently nominated for the $100,000 Manning Innovation Award for their work on ZMapp, a promising antibody-based therapeutic to treat the Ebola virus disease.

A San Diego company called Mapp Biopharmaceuticals has licensed the intellectual property from the Public Health Agency of Canada for ZMapp.

Until now, there has been no licensed treatment or vaccine for Ebola.

As well, the team of Winnipeg scientists has developed a promising Ebola vaccine called VSV-EBOV that's been licensed to NewLink Genetics that is also in clinical trials in West Africa.

ZMapp is the first experimental Ebola drug used in an outbreak and considered the most promising of a number of experimental treatments. (FDA). Because of limited supply, only seven patients were treated, and five recovered fully. But since it is not a controlled environment, those results are not sufficient to allow widespread distribution.

The good news is the WHO said there have been only two new reported cases in Liberia since late February and none since the third week in March. And the number of new cases in Sierra Leone and Guinea was down to nine in each country in its most recent report for the seven-day period ending May 3.

But that may mean enrolment in the ZMapp trial will fall short.

"It is a good problem to have," Kobinger said.

Zeitlin said there are paths to get the drug approved by the FDA when sufficient clinical trials are not possible.

"It would be a wonderful public-health outcome," Zeitlin said in an interview from his San Diego office. "The sooner the outbreak is over, the better."

Kobinger believes ZMapp will not require a large patient set because of the excellent results in the small compassionate-use sample.

He does not want to jump the gun or compromise the scientific process that's required for widespread use of the treatment, but as one of the world's leading scientists in the field at the forefront of finding a treatment during this latest and worst outbreak, Kobinger's future plans are noteworthy.

"I HAVE told my group I want to work on something else now," he said. "I do not want to spend five years to improve this product by five per cent... when, for instance, we do not have a treatment equivalent for Marburg or Lassa fever or for Sudan Ebola. I think it would be a much better investment in time to go after those new targets."

And Kobinger will be making that move in the most satisfying way possible for a medical researcher.

"It was my dream — I think it is the dream of most scientists — to develop

incurable viruses

Two of the three antibodies in the ZMapp cocktail originated from the work of Kobinger, Qui and their team in Winnipeg. In February, the U.S. National Institute of Allergy and Infectious Diseases (NIAID) started clinical trials in Liberia, Africa, to obtain safety and efficacy data.

Additional sites are expected to start in Sierra Leone and Guinea.

It's not clear how long it will take or when the data results will be available, but Kobinger is going to come back from his Deep South boating excursion and start working on something other than Ebola for the first time in more than 10 years.

That's because he's convinced the ZMapp treatment will successfully treat those suffering from Ebola.

"We think it is done," said Kobinger on board his boat in northern Mississippi. "I am a very skeptical person and very careful before I say it works... and I have been waiting and waiting and waiting. I feel very strongly about how good this treatment is. I have no question about it."

Ebola has an average fatality rate of 50 per cent but it can be as high as 90 per cent. Up to the end of April, the latest Ebola outbreak — the worst in history — had caused 10,899 deaths, reported the World Health Organization (WHO).

Since last October when their article, *Reversion of advanced Ebola virus disease in non-human primates with ZMapp* appeared in *Nature*, Kobinger, Qui and their collaborators, especially Larry Zeitlin of Mapp Biopharmaceuticals in San Diego, have been at the forefront of efforts to produce the cocktail and get it into the field.

The typical process to work a new drug through the regulatory process can take months, usually years.

Approval for compassionate use of ZMapp was obtained from the U.S. Food and Drug Administration

something that can save lives... With each patient that recovered after treatment, for me and others in the lab, it has been magical."

Being at the epicentre of the cure for something as frightening and deadly as Ebola is a rare opportunity.

Some might also believe it is a chance to strike it rich.

But that is the antithesis of Kobinger's attitude. He sounds proud when declaring he does not have his name on any patents.

"I have no financial links," he said. "I am not interested. I am trying to make a contribution."

Matthew Gilmour, the newly installed scientific director general of the National Public Health Laboratories, responsible for the Winnipeg lab, said the work Kobinger and Qui have done is exactly what the lab is supposed to do.

"We are exceptionally proud of the work of our team," he said.

Among other assets, it is the only Level 4 bio-containment lab in the country that can handle dangerous pathogens such as the Ebola virus. Gilmour said the lab has had a great relationship with global organizations such as the WHO as well as provincial health labs.

He said the lab has put 17 two-person teams on the ground to assist with the Ebola outbreak.

"It certainly has brought profile to the capabilities we have always had here," he said. "It extends beyond just our special pathogens programs."

Mapp Biopharmaceuticals is in control of the development of the ZMapp, and that's fine with Kobinger.

"They are fantastic," he said. "I cannot tell you how impressed I have been with them."

Zeitlin said of his relationship with Kobinger, "We are like brothers now."

martin.cash@freepress.mb.ca

Gary Kobinger wants his next project at the National Microbiology Lab on Arlington Street to focus on diseases such as Marburg, Lassa fever or Sudan Ebola.

Public sector funding for Ebola research and outreach

- On Nov. 3, 2014, the Canadian government committed $23.5 million to support research and development of the Ebola vaccine and monoclonal antibody treatments for Ebola.
- In total, Canada has committed more than $110 million to support health, humanitarian and security interventions to respond to the outbreak and for further research and development of Ebola medical countermeasures.
- The U.S. Biomedical Advanced Research and Development Authority will provide funding as well as access to subject-matter expertise and technical support for manufacturing, regulatory, and non-clinical activities through a $24.9-million, 18-month contract with Mapp Biopharmaceutical Inc. It can extend the contract up to a total of $42.3 million.

Manitobans show smarts

Among nominees for Manning Award

By Martin Cash

MANITOBA is punching above its weight again with three of the 28 final nominees for the $100,000 top prize in this year's Ernest C. Manning Innovation Awards.

The Manning Awards recognize Canadian innovators who improve the lives of Canadians and others around the world through their innovations. One criterium that separates these awards from other innovation or academic awards is there has to be evidence of commercialization.

Two Manitobans won the national award last year — Mark Torchia and Richard Tyc — for their work that has become the underlying technology used by Monteris Medical Inc., makers of the NeuroBlate, a device that allows surgeons to treat patients with deep-seated brain tumours.

Harry Schulz, a Manitoba trustee of the Manning Foundation, said the objective of the award is to draw attention to great Canadian innovation and encourage others.

"On a regional level, we want to promote excellence by Manitobans," he said.

"It can be a long road to success. To give recognition to people who are at this level is an important thing."

The three groups of Manitoba nominees are Gary Kobinger and Xiangguo Qiu from the National Microbiology Laboratory; Shane Yanke, Eric Himbeault and Andrew Winton for their work at Cogmation Robotics; and Brad Ross, founder of PTDial.

The nominees will be recognized by the Winnipeg Chamber of Commerce today. Schulz said the chamber recognizes the attributes the Manning Awards promote are compatible with its objectives of creating technology companies in Manitoba that go on to become job creators and wealth generators in the province.

Gary Kobinger and Xiangguo Qiu: Kobinger and Qiu have led a team of scientists at the National Microbiology Laboratory, at the Public health Agency of Canada, in Winnipeg in more than a decade's search to find a treatment against the Ebola virus infection. They discovered and developed highly specific monoclonal antibodies that targeted and neutralized Ebola within the body and determined a cocktail of three antibodies was effective in animal studies. The cocktail, called ZMapp, was successfully tested in trials in 2015 at the tail end of the last Ebola outbreak in West Africa. Ongoing development with commercial partners in Canada and the U.S. is hoped to lead to full licensure in 2016.

Shane Yanke, Eric Himbeault and Andrew Winton: The three designed the Virtual Robotics Toolkit for Cogmation Robotics. Yanke and Himbeault continue to be associated with Cogmation and Winton works there full time. Designed for use with Lego Mindstorms robots, the Virtual Robotics Toolkit allows students and teachers to program and control a simulated replica of the physical robot using the same tools that are used to program the real thing. Jack Peterson, the CEO of the company, said, "Initially, we had different customers. We did not find a big market until we met the president of Lego education in the U.S. who wanted us to do a simulator for his robot." Yanke, Himbeault and Winton developed that. So far, Peterson said, the biggest market is in China, but the tool kit is also being used in schools in Winnipeg, Toronto and elsewhere.

Brad Ross: Ross, the founder of PTDial is a physiotherapist who wanted to find a balance between protection and comfort when it comes to dealing with the pain and discomfort of tennis and golfer's elbow. But since the pain was always variable depending on what the patient was doing, it seemed clear to Ross adjusting the pressure on a brace was important. "The more pressure you have, the more protection you get, and the less pressure the more comfort," Ross said. "How can you manage the two and maximize both? The only way is to have adjustability." Ross started working on the PTDial, which includes a patented dial-adjusting feature, about nine years ago and has patents in Canada, the U.S. and several other countries and has been selling it for four years.

Manning nominee Manas Banerjee, of XiteBio Technologies Inc., developed a new formulation of microbial inoculants to enhance plant growth and crop yields.

MARTIN CASH

THE stereotypical Canadian does not boast about achievements. That's probably why the annual $100,000 Manning Innovation Award is not more well known than it should be.

It has been around since 1980 and Manitobans have won it a couple of times, including two years ago when Mark Torchia and Richard Tyc won for their joint development of the NeuroBlate System, and in 2010 by Werner Ens and Ken Standing for their work in the field of mass spectrometry.

The award honours innovators who have developed and successfully marketed a new concept, process or procedure.

This year, there are two groups of Manitoba nominees for the $100,000 award: Gary Kobinger and Xiangguo Qiu for their work at the National Microbiology Lab on the development of a treatment for the Ebola virus, and Manas Banerjee, of XiteBio Technologies Inc., who developed a new formulation of microbial inoculants to enhance plant growth and crop yields.

This is the third time Kobinger and Qiu have been nominated. The timing of today's announcement (Qiu and Banerjee were to be on hand at a Winnipeg Chamber of Commerce event) is significant for Kobinger and Qiu because a brand-new outbreak of Ebola has just occurred.

The World Health Organization has confirmed three deaths earlier this week in a remote northeastern province of the Democratic Republic of Congo.

In an interview at his office at Université Laval in Quebec City, where he is now based, Kobinger said it would be hard to find anyone at the Level Four lab at Winnipeg's National Microbiology Lab who had not contributed to the Ebola research over the past 10 years.

The results of some of that work will quite likely come into play in the coming weeks in Congo. Kobinger said both the rVSV vaccine and ZMapp treatment — both of which include substantial contributions from Kobinger and Qiu's team — could be crucial in the current outbreak.

The rVSV vaccine has been through clinical trials and the ZMapp has had significant positive results in a trial in 2016. There was compassionate use of both with good results in the massive outbreak in West Africa in 2014-15.

Intense collaborations with partners in Canada, the U.S. and various agencies worldwide contributed to generate a stockpile of ZMapp for international public health security.

"The bottom line is that ZMapp reached 92 per cent success (in the small clinical trial in 2016) and as of today with an ongoing outbreak the one treatment that is up there first on the line is ZMapp," he said.

Kobinger continues to conduct research into the ecology of the virus and how it circulates in the species that carry it.

"We still don't understand why it appears in humans," he said. "We are always caught off guard."

He is indifferent to the commercial ramifications of the development of the treatment.

Some say because Ebola outbreaks are so rare and that those infected are, sadly, the poorest of the poor in the poorest countries, discovering treatments has not been a top priority for pharmaceutical companies.

That makes the work that Kobinger and Qiu's team undertook even more noteworthy.

Kobinger said what may be even more substantial about their work is that it has provided the foundation for the recent explosion of monoclonal antibody therapies as a new way to look at treatments of all sort of infectious diseases. He said so much work is being done around the world that he can't even keep up.

As for the Manning Award, he said. "It would be fantastic to win on the third try."

This is the first time Banerjee has been nominated for the award. But the Winnipeg scientist/entrepreneur is another classic example of dedicated scientific research done without being distracted by the demands of quarterly returns to shareholders.

In his case, Banerjee has been doing research in cell microbiology for about 25 years and has developed a sustainable business over the past six years with more than a dozen employees and a growing — and loyal — customer base across Canada and the U.S.

Banerjee works in the field of microbial inoculants and has competitors with names like Bayer, BASF and Dupont.

His innovative technology is called AGPT (Advanced Growth Promoting Technology). Whereas the product from the competition will try to supplant native soil microbes, XiteBio's inoculants are designed to work with the microbes that are already there.

"We came up with a formulation, AGPT, that creates a synergy," he said. "The inherent natural reaction for the existing microbes is to kick out the newly introduced bacteria (that will promote plant growth). Our product is the opposite. Rather than fight against them, we work with them."

Banerjee is aware of the challenges and demands agricultural producers face and does not want to be part of an exercise that does not produce actual benefits for the farmers.

Even though he has had many offers from the larger agricultural nutrient companies to buy his company, he said he has no desire to sell.

"When you work in a private company like mine, you have to innovate, you have to think outside the box," he said.

"Sometimes it is not that easy. Sometimes you have to take the path which the other guys might not take."

Banerjee said he is gratified by the growing number of repeat customers who not only use his product each year but double their order.

For someone whose work is appreciated by many, but does not have the high profile of the more well-known brands, being up for a Manning Award is a big deal.

"It is definitely an honour," he said.

MANNING AWARDS PROVE ALBERTA BREEDS INNOVATION

Three of four winners this year come from province, and none are in energy sector

DEBORAH YEDLIN

If anyone needs proof that innovation and entrepreneurship are thriving in Alberta, they should look no further than the Manning Innovation Awards.

The brainchild of former Alberta Energy Company chief executive David Mitchell, the awards were presented for a 36th year Wednesday night in Toronto. Three of the four laureates call Alberta home: two from Calgary and one from Edmonton.

None are in the energy space.

They instead inhabit the environmental, agricultural and tech spheres. The fourth laureate, receiving the Principal Award, was two individuals — doctors Gary Kobinger and Xiangguo Qiu, who developed the ZMApp antivirus for treatment of Ebola.

Gary Kobinger

Ebola treatment creators to get innovation award

GARY Kobinger and Xiangguo Qiu, research scientists from the National Microbiology Lab, have been named to the group of six winners of the 2018 Governor General's Innovation Awards (GGIA).

The awards celebrate outstanding Canadian individuals, teams and organizations whose transformative work help shape our future and positively impact our quality of life.

Using unorthodox, cutting-edge technologies that went against prevailing scientific opinion, doctors Kobinger and Qiu created ZMapp to treat patients with the Ebola virus. ZMapp comprises a cocktail of monoclonal antibody therapies that act like missiles targeting the outer shell of the Ebola virus, preventing it from replicating. Its first human applications resulted in the full recovery of two medical missionaries and 25 first responders and residents during the 2014 Ebola outbreak in Liberia. Since then, ZMapp has been driving studies into the efficacy of monoclonal antibody therapies against HIV, Lassa, Marburg and other infectious illnesses.

With a recent outbreak of the disease in the Congo, the importance of Kobinger and Qiu's work will be further felt as the World Health Organization just announced its intention to bring in thousands of doses of an experimental vaccine — that Kobinger and Qiu contributed important work on — into the region.

Gov. Gen. Julie Payette will present the awards to the winners during a ceremony on May 23 at Rideau Hall in Ottawa.

TOM BLACKWELL

RESPECTED WINNIPEG EBOLA-DRUG SCIENTIST AT CENTRE OF RCMP INVESTIGATION

Heinz Feldmann has known and worked with Xiangguo Qiu for years, and to this day says he has nothing but respect for his fellow microbiologist.

Indeed, Qiu won global accolades for her part in developing an experimental new drug for treating Ebola virus, most of the inquiry done at her high-security lab in Winnipeg.

So Feldmann says he was taken aback Monday to see a media report that the scientist and her entire research team, all from China, had been escorted out of the federal government's National Microbiology Laboratory (NML) last week and reported to the RCMP.

"I still hope that this is a big misunderstanding," said the former head of the lab's special pathogens program, where Qiu worked. "She is a great researcher, she has been a great collaborator, she has been a great interacter in the field. I can't say anything bad about her."

Feldmann, now chief of the U.S. National Institutes of Health laboratory of virology in Montana, stressed that he had no personal knowledge of the reported events.

See LAB on NP3

CBC-TV said that Qiu, as well as husband and NML scientist Keding Cheng and her students had been forcibly dispatched from the facility on July 5, a fact the National Post could not independently confirm.

Eric Morrissette, a spokesman for the Public Health Agency of Canada, would not comment on whether she had been dismissed, citing privacy concerns.

But he said the agency is looking into an "administrative matter," and advised the RCMP on May 24 of "possible policy breaches" at the lab.

The organization is "taking steps to resolve it expeditiously," said Morrissette in a statement. "There is no employee from the NML under arrest or confined to their home." He also said the public is not at risk and that the work of the lab continues.

An RCMP spokesman confirmed to Reuters news agency it had received a referral from the agency, but refused to comment on its investigation. A University of Manitoba spokesman told Reuters that Qiu's non-paying adjunct professorship had been suspended "pending an RCMP investigation."

With the government releasing so few details, it is unclear what might be behind the unusual episode.

But in the U.S., at least, security agencies have recently put a magnifying glass on researchers and students with ties to China, amid fears that Beijing is overseeing widespread theft of intellectual property and trade secrets.

A number scientists south of the border — and one now-retired professor at McGill University — have been charged under a controversial new "China Initiative" of the U.S. Justice Department, which critics call a racially biased witch hunt.

The Ebola drug partly discovered by Qiu is being developed by a California company, and three potentially competing medicines are also in the works.

But Feldmann said he doubts that treatments for an illness that afflicts relatively few people, with little pharmaceutical buying power, would be the subject of economic espionage.

"To make money off these rare diseases, there would be better things to do if you really wanted to make money," he said.

Regardless, there are few more high-profile figures still at the microbiology lab, whose level-four unit is one of a small number worldwide that work with the world's most dangerous pathogens, including Ebola and other hemorrhagic fevers.

Qiu worked with Gary Kobinger, who succeeded Feldmann as head of special pathogens but has since left the lab himself, on so-called monoclonal antibody treatments for Ebola, their findings coming to the fore internationally when the lethal virus swept through West Africa in 2014 and 2015.

Their discoveries make up two of three elements in the drug ZMapp, which has had promising results in limited trials and case-by-case in compassionate use, but has yet to receive approval.

According to a 2014 conference biography, Qiu obtained her Master's in immunology in 1990 at Tianjin Medical University.

She moved to Houston in 1996, then moved to Cancer Care Manitoba the next year as a research associate.

National Post

[HN00R5][GDrive]

2019 (July 19) - "Mystery surrounds ouster of Chinese researchers from Canadian laboratory" from AAAS (American Association for the Advancement of Science)

See [HP002G][GDrive]

Canadian researchers are reacting with puzzlement to the news that a "policy breach" has caused the nation's only high-containment disease laboratory to bar a prominent Chinese Canadian virologist, her biologist husband, and a number of students from the facility.

On 5 July, officials at the **National Microbiology Laboratory (NML) in Winnipeg, Canada**, escorted **Xiangguo Qiu**, biologist **Keding Cheng**, and an unknown number of her students from the lab and revoked their access rights, according to Canadian media reports. The Public Health Agency of Canada, which operates the lab, confirmed it had referred an "administrative matter" matter to the Royal Canadian Mounted Police, but said it would not provide additional details because of privacy concerns.

A number of observers have speculated that case involves concerns about the improper transfer of intellectual property to China. (All of the researchers involved are believed to be Asian.) **But Frank Plummer, a former scientific director of NML who left in 2015, says the lab isn't an obvious target for academic or industrial espionage**. ***"There is nothing highly secret there, and all the work gets published in the open literature," he says. "I don't know what anyone would hope to gain by spying."***

The lab works in a wide range of biomedical fields. **Qiu is known for helping develop ZMapp, a treatment for Ebola virus that was fast-tracked through development during the 2014–16 outbreak in West Africa.** She has repeatedly been honored for her work on that project, including with a Governor General's Innovation Award last year.

"While I was there [Qiu] was always highly regarded as a scientist," says Plummer, adding that he was "shocked and puzzled" when he heard she was being investigated. "She maintained connections with China, but as far as I knew she was a regular Canadian scientist."

Cheng, Qiu's husband, also worked as a biologist at NML. And both researchers held adjunct faculty positions at the University of Manitoba in Winnipeg. It says it has terminated their positions and reassigned their students as a result of the investigation.

Neither Qiu nor Cheng could be reached for comment.

The development comes at a sensitive time for relations between Canada and China. In December 2018, Canada arrested Chinese Huawei executive Meng Wanzhou at the request of the United States. In retaliation, China has arrested two Canadian men on espionage charges and sentenced a third to death for drug offenses.

It also comes as the U.S. National Institutes of Health (NIH) has raised concerns that some grantees have failed to disclose ties to China and other nations, or improperly shared confidential information. The concerns have led several universities to oust researchers who are ethnic Chinese and return grant funds to NIH. The crackdown has raised concerns among the Chinese American community of racial profiling. In Canada, the nation's Security Intelligence Service has long warned of state-sponsored espionage, and in 2014, the Canadian government alleged that China was behind a cyberattack on Canada's National Research Council.

2019 (Dec) - "China's Biological Warfare Programme and the Curious Case of Dr. Xiangguo Qiu" from "Manohar Parrikar Institute for Defence Studies and Analyses (MP-IDSA)"

[HI000K][GDrive]

In July 2019, a rare event occurred in Canada, whereby a group of Chinese virologists were forcibly dispatched from the Canadian National Microbiology Laboratory (NML) in Winnipeg, a facility they worked in, running parts of the Special Pathogen Programme of Canada's Public Health Agency.1 Experimental infections – including aerogenic ones – of monkeys with the most lethal viruses found on Planet Earth comprise nearly a routine therein. Four months earlier, a shipment of two exceptionally virulent viruses dealt with in the NML – Ebola and Nipah viruses – was on its way from NML, ended in China, and has thereafter been traced and regarded to be improper, specifically put as "possible policy breaches", or rather but an "administrative issue", ostensibly.2

Yet the scope of this incident is much wider, in actuality. The main culprit seems to be Dr. Xiangguo Qiu, an outstanding Chinese scientist, born in Tianjin. Heading until recently the Vaccine Development and Antiviral Therapies section of the Special Pathogens Programme, she primarily received her medical doctor degree from Hebei Medical University in China in 1985 and came to Canada for graduate studies in 1996.3 Later on, she was affiliated with the Institute of Cell Biology and the Department of Pediatrics and Child Health of the University of Manitoba, Winnipeg, not engaged with studying pathogens.4 **But a shift took place, somehow. Since 2006,5 she has been studying powerful viruses, Ebola virus foremost, in the NML.** The two viruses shipped from the NML to China – Ebola and Nipah – were studied by her in 2014, for instance (together with the viruses Machupo, Junin, Rift Valley Fever, Crimean-Congo Hemorrhagic Fever and Hendra).6 Yet utmost attention has been paid to Ebola, with the highly legitimate aim of developing effective prophylaxis and treatment for infected people. Inevitably, her works included a variety of Ebola wild strains – among them the most virulent one, with 80% lethality rate – and much relied on experimental infections of monkeys, including via the airways.7 Remarkable achievements were attained, indeed, and Dr. Qiu accepted the Governor General's Innovation Award in 2018.

So far so good, seemingly. But the collateral Chinese plexus cannot be ignored. Married to a Chinese scientist – Dr. Keding Cheng, also affiliated with the NML (specifically the "Science and Technology Core"), and primarily a bacteriologist who shifted to virology – Dr. Qiu frequently visited and maintained tight

bonds with China, generally speaking, and many Chinese students joined her works in the NML during the recent decade, coming from a notable range of Chinese scientific facilities. Nonetheless, among the latter there are four facilities that have been regarded to possess parts of the Chinese biological weapons alignment,[8] namely:

- Institute of Military Veterinary, Academy of Military Medical Sciences, Changchun[9].
- Center for Disease Control and Prevention, Chengdu Military Region[10].
- Wuhan Institute of Virology, Chinese Academy of Sciences, Hubei[11].
- Institute of Microbiology, Chinese Academy of Sciences, Beijing[12]

All of the four mentioned facilities collaborated with Dr. Qiu within the context of Ebola virus, yet the Institute of Military Veterinary joined a study on the Rift Valley fever virus too,[13] while the Institute of Microbiology joined a study on Marburg virus too.[14] Noticeably, the drug used in the latter study – Favipiravir – has been earlier tested successfully by the Chinese Academy of Military Medical Sciences, with the designation JK-05 (originally a Japanese patent registered in China already in 2006), against Ebola and additional viruses.[15]

However, the studies by Dr. Qiu are considerably more advanced and fruitful, in certain aspects. They are apparently vital for the Chinese biological weapons developing, in case Ebola, Nipah, Marburg or Rift Valley fever viruses are included therein, which is a plausible postulation; let alone the wild type viruses in themselves. And it is of note that only Nipah virus is naturally found in China or neighboring countries. Collectively, then, the interface between Dr. Qiu and China has a priori been highly suspicious. On top of it, the shipment of the two viruses from NML to China apparently generated an alarm, beyond its seeming inappropriateness. And an unavoidable question is whether previous shipments to China of other viruses or other essential preparations, took place from 2006 to 2018, one way or another.

At any rate, the controversial shipment brought about the entering of information technology specialists into Qiu's office after hours, for her computer. Consequent to the incident, security access for Dr. Qiu, her husband and the Chinese students was revoked. Her regular trips to China also started being denied.[16] Notably, Dr. Qiu made at least five trips over the school year 2017-18 to the above mentioned Wuhan National Biosafety Laboratory of the Chinese Academy of Sciences,[17]which was certified for BSL4 in January 2017. Moreover, in August 2017, the National Health Commission of China approved research activities involving Ebola, Nipah, and Crimean-Congo hemorrhagic fever viruses at the Wuhan facility, and in March 2019, the Chinese published their tour de force.[18]

Jens Stoltenberg, the secretary-general of NATO, said at a news conference he couldn't comment on this specific case but appeared to suggest the possibility of espionage. "What I can say in general is that we have seen increased efforts by the nations to spy on NATO allies in different ways," he noted.[19] Connectedly or not, Dr. Qiu collaborated in 2018 with three scientists from the US Army Medical Research Institute of Infectious Diseases, Maryland, studying post-exposure immunotherapy for two Ebola viruses and Marburg virus in monkeys; a study supported by the US Defense Threat Reduction Agency.[20]

Finally, the multiplicity of the Chinese grants – all of on a national level – supporting the works done under the leading of Dr. Qiu in the NML is rather intriguing; included are:

- National Key Program for Infectious Disease of China
- National Key Research and Development Program of China
- National Natural Science Foundation of China International Cooperation and Exchange Program
- Special Foundation of President for Ebola virus research from the Chinese Academy of Sciences.
- President's International Fellowship Initiative from the Chinese Academy of Sciences
- China National Key Subject of Drug Innovation
- Youth Innovation Promotion Association of the Chinese Academy of Sciences
- National Natural Science Foundation Award, Ministry of Science and Technology
- National Science and Technology Major Projects
- Beijing Advanced Innovation Center for Structure Biology
- Major Program of the National Natural Science Foundation of China.

Certainly an impressive list.

In sum, there is still a possibility that Dr. Qiu and her husband will return to work in the NML. Yet beyond the administrative dimension of this complicated affair, it is largely also a matter of intelligence analysis and assessment, which might constitute a 'gray area'. A challenge for the Canadian Security Intelligence Service. Time will tell, sooner or later.

2020 (Jan 29) - "China and Viruses: The Case of Dr. Xiangguo Qiu" (Begin-Sadat Center for Strategic Studies)

See [HI000J][GDrive] / **By** Lt. Col. (res.) Dr. Dany Shoham

[HI000K][GDrive]

EXECUTIVE SUMMARY: In July 2019, a rare event occurred in Canada. Suspected of espionage for China, a group of Chinese virologists was forcibly evicted from the Canadian National Microbiology Laboratory (NML) in Winnipeg, where they had been running parts of the Special Pathogen Program of Canada's public health agency. One of the procedures conducted by the team was the infection of monkeys with the most lethal viruses found on Earth. Four months prior to the Chinese team's eviction, a shipment containing two exceptionally virulent viruses—Ebola and Nipah—was sent from the NML to China. When the shipment was traced, it was held to be improper and a "possible policy breach."

The scope of the 2019 incident involving the discovery of a possibly serious security breach at Canada's National Microbiology Laboratory (NML) in Winnipeg is much broader than the group of Chinese virologists who were summarily evicted from the lab. The main culprit behind the breach seems to have been Dr. Xiangguo Qiu, an outstanding Chinese scientist born in Tianjin.

Until recently the head of the Vaccine Development and Antiviral Therapies section of the Special Pathogens Program, Qiu received her MD degree from Hebei Medical University in China in 1985 and came to Canada for graduate studies in 1996. She was later affiliated with the Institute of Cell Biology and the Department of Pediatrics and Child Health at the University of Manitoba, Winnipeg. She was not engaged in the study of pathogens while at that institute.

But a shift took place in Qiu's research work. Ever since 2006, she has been studying powerful viruses—Ebola most of all—at the NML. Both of the viruses that were surreptitiously shipped from the NML to China were studied by Qiu in 2014 (as well as other viruses, including Machupo, Junin, Rift Valley Fever

that were surreptitiously shipped from the NML to China were studied by Qiu in 2014 (as well as other viruses, including Machupo, Junin, Rift Valley Fever, Crimean-Congo Hemorrhagic Fever, and Hendra). But she paid greatest attention to Ebola for the entirely legitimate aim of developing effective prophylaxis and treatment for the infected.

Inevitably, Qiu's work included a variety of Ebola wild strains—among them the most virulent, which has an 80% lethality rate—and relied heavily on experimental infection of monkeys, including via the airways. She made remarkable strides, and was granted the Governor General's Innovation Award in 2018.

So far so good—or so it seems.

Qiu is married to Chinese scientist Keding Cheng, a bacteriologist who shifted to virology and who is also affiliated with the NML. Qiu maintains a close bond with China and visits frequently, and many Chinese students from a notable range of Chinese scientific facilities have joined her at the NML over the past decade.

Of those facilities, four are believed to be involved in Chinese biological weapons development. They are:

- Institute of Military Veterinary, Academy of Military Medical Sciences, Changchun
- Center for Disease Control and Prevention, Chengdu Military Region
- Wuhan Institute of Virology, Chinese Academy of Sciences, Hubei
- Institute of Microbiology, Chinese Academy of Sciences, Beijing

All four facilities collaborated with Qiu on her Ebola research. The Institute of Military Veterinary also joined a study on the Rift Valley fever virus, while the Institute of Microbiology joined a study on the Marburg virus. Notably, the drug used in the latter study—Favipiravir—has been successfully tested by the Chinese Academy of Military Medical Sciences against Ebola and other viruses. (The drug has the designation JK-05; it is originally a Japanese patent registered in China in 2006.)

The Chinese interest in Ebola, Nipah, Marburg, and Rift Valley fever might possibly be beyond scientific and medical needs. Significantly, only the Nipah virus is naturally found in China or neighboring countries. That being the case, the interface between Qiu and China is a priori highly suspicious.

The shipment of the two viruses from NML to China is alarming unto itself, but it also raises the question of what other shipments of viruses or other items might have been made to China between 2006 and 2018.

Qiu made at least five trips over the academic year 2017-18 alone to the above-mentioned Wuhan National Biosafety Laboratory of the Chinese Academy of Sciences, which was certified for BSL4 in January 2017. In August 2017, the National Health Commission of China approved research activities involving the Ebola, Nipah, and Crimean-Congo hemorrhagic fever viruses at the Wuhan facility, and in March 2019, the Chinese published their tour de force.

When the shipment from Canada was uncovered, security access was revoked for Qiu, her husband, and the Chinese students. IT specialists entered Qiu's office after hours to gain access to her computer, and her regular trips to China were halted.

Jens Stoltenberg, the secretary-general of NATO, said at a news conference that he can't comment on the case, but appeared to suggest the possibility of espionage. "What I can say in general is that we have seen increased efforts by the nations to spy on NATO allies in different ways," he said.

Qiu's research has not only been conducted on behalf of Canada and China. In 2018, she collaborated with three scientists from the US Army Medical Research Institute of Infectious Diseases, Maryland, studying post-exposure immunotherapy for two Ebola viruses and Marburg virus in monkeys. Those activities were part of a study supported by the US Defense Threat Reduction Agency.

The multiplicity of Chinese grants, all on the national level, supporting the work done under Qiu's lead at the NML is impressive:

- National Key Program for Infectious Disease of China
- National Key Research and Development Program of China
- National Natural Science Foundation of China International Cooperation and Exchange Program
- Special Foundation of President for Ebola virus research from the Chinese Academy of Sciences
- President's International Fellowship Initiative from the Chinese Academy of Sciences
- China National Key Subject of Drug Innovation
- Youth Innovation Promotion Association of the Chinese Academy of Sciences
- National Natural Science Foundation Award, Ministry of Science and Technology
- National Science and Technology Major Projects
- Beijing Advanced Innovation Center for Structure Biology
- Major Program of the National Natural Science Foundation of China

It is still possible that Qiu and her husband will return to work at the NML, but a good deal of intelligence analysis and assessment will be required. The Canadian Security Intelligence Service has a serious challenge on its hands.

2020 (Jan 27) WUHAN VIROLOGY INSTITUTE, CHINESE BIOLOGICAL WARFARE AND CHINESE-CANADIAN SPY

See [HW002C][GDrive]

The CCP regards the intellectual property theft as a critical strategy for its rise becoming a great nation and its invasion of the world. Many Chinese researchers are either the CCP's spies or lacking moral consciousness. Some of them cannot resist the temptation of huge benefits provided by the CCP and some of them feel obligatory with the calling of patriotism. They use the convenience of their work and research in the West to steal technologies and stealthily, provide them to the CCP. In this incidence, two Chinese-Canadian scientists secretly stole biological viral samples, which provided valuable data and samples for viral research, to the CCP, and should be hold responsible for the outbreak of coronal virus in Wuhan.

Twitter 1:

Chinese Communist Party masters and develops deadly bacteria as a weapon of Biological warfare — (Israel Military Intelligence Agency). See how they have cultivated the export of "talent" to steal Western intellectual Property during decades.

In July 2019, the "spy" couple and their Chinese students were taken away from the **Manitoba National Microbiology Laboratory**. The University of Manitoba announced the dismissal of the Qiu couple.

Please look down at their relationship with this Wuhan Coronavirus.

Chinese bacterial thief Qiu Xiangguo and her husband Chen Keding

Twitter 2:

Qiu Xiangguo was taken out of a Canadian laboratory, former colleague said shocked

The National Microbiology Laboratory in which Qiu Xiangguo onced worked is the only Pathogen Level 4 laboratory in Canada. It is one of the few laboratories in North America that has the ability to handle pathogens such as Ebola virus which needs the highest level of seal. It is also one of the 15 laboratories of Pathogen Level 4 in the world and the only one in Canada.

Twitter 3:

- She was born in 1964
- In 1980, she was admitted to Hebei Medical College at the age of 16
- Graduated from Hebei Medical University in 1985
- Postgraduate Student of Immunology, Tianjin Medical University, in 1990
- In many materials, she covered up visiting at the MD Anderson Cancer Center in Houston in 1996 as a guest scientist
- In 1997, she was assistant research fellow in University of Manitoba Cancer Treatment Center
- In 2003, she joined Special Pathogen Project of the National Microbiology Laboratory

Twitter 4:

Her husband, Cheng Keding is also under investigation. He is a biologist and has even participated in the treatment and defense of Ebola virus. He has published papers about AIDS, SARS and coliform bacteria. The couple has been working with a team of Chinese students and cooperated with Wuhan Institute of Virology.

Twitter 5:

About MD Anderson and Yueyin venture capital and **Yueyin Datong (Tianjin) Asset Management Co., Ltd.** Look, these belong to **Wang Qishan**. The Qiu Xiangguo couple has always been in touch with Tianjin Medical College.

Twitter 6:

The latest Canadian media's investigation found that just two months before Dr. Qiu was taken away, Canada national microbiology laboratory she worked in sent live **Ebola** and **Henipavirus** to China with the via Air Canada. The destination was Beijing.

Before the incident, Qiu Xiangguo served as the leader of the laboratory's special virus project team-vaccine development and antiviral treatment group, and was responsible for research work related with Ebola virus.

Twitter 7:

The viruses were shipped to the Chinese Academy of Sciences bypassed the laboratory's procedure and protocols and without additional documentation to protect Canadian intellectual property. Researchers engaged in cutting-edge high-containment research at the National Microbiology Laboratory are not allowed to ship anything to other national laboratories without consulting with the Intellectual Property Office and reaching a material transfer agreement.

Twitter 8:

In 1996, she entered the United States as a member of Thousand Talents Program, and then moved to the Canadian laboratory. Over the years, Qiu Xiangguo has recruited a large number of Chinese students and visited to Chinese universities regularly. Look! The Ebola antibodies that she developed together with Tsinghua. The weird thing is **ZMapp** is a California company producing vaccines !! Check if it belongs to **Jiang Mianheng**? !!

Twitter 9:

According to travel documents obtained by the Canadian CBC, Qiu Xiangguo traveled to China at least five times in 2017-2018, including providing training program for science and technology personnel in a newly established P4 laboratory in China, which is engaged in the most deadly pathogen research.

Wuhan P4 Bio Lab ! ? !!

Twitter 10:

Look at here! Wuhan Virus Laboratory is accredited to conduct research on three types of viruses: Ebola, Congo-Crimea hemorrhagic fever and Henipavirus.

Isn't all smuggled out of Canadian laboratories by Qiu Xiangguo? !!

Twitter 11:

Wuhan Wuhan Wuhan

Wang Qishan, Meng Jianzhu

The Canadian Mounted Police investigated Qiu Xiangguo in July and took her away from the laboratory. Newly exposed documents show that Qiu Xiangguo was invited to the Wuhan National Biosafety Laboratory of the Chinese Academy of Sciences for two consecutive years, twice a year for up to two weeks at a time. Public Health Canada says Qiu's actions could be "violating policies."

Twitter 12:

The Chinese Communist Party's cover blows up.

The United States and Canada already have the intelligence.

The document obtained by the CBC showed that "Qiu's visit was funded by a third party", but the third party's name was erased from the document. **During her trip from September 19th to 30th, 2017, she also met with collaborators in Beijing, and the names of the participants in the meeting were also erased**.

Twitter 13:

When the Chinese government introduced Qiu, it misled people to believe that she invented the ZMapp's drug.

Police documents show that Xiangguo also visited some academic institutions such as the Chinese Academy of Sciences, Tsinghua University, and the Chinese Academy of Medical Sciences, and gave speeches at several conferences when she visited China.

Twitter 14:

This 4/5/2018 CCTV's report is the proof. Virus is flowing from Wuhan bio laboratory. And the Chinese Communist party has a vaccine. So why not give it to the patients? When are you going to "fight fires"?

Twitter 15:

In 2014, The Canadian government claims that China leads the cyber attack on the Canadian National Research Council.

In fact, the Qiu couple is just two examples in the Chinese Thousand Talents Program. There are more scientists there stealing intellectual properties for the CCP.

2020 (Feb) - Factcheck-AFP - Chinese 'spies' did not steal deadly coronavirus from Canada

See [HW002D][GDrive]

Websites and social media users claim that the new coronavirus discovered in the city of Wuhan may have been created in Canada and stolen by Chinese spies. This is false; Canadian health and federal police officials say it has no factual basis, and experts say evidence indicates the virus has a natural origin.

"Corona virus developed in Canada and stolen by China?" reads the headline of this article from January 22, 2020. It appears to be the first of a series of such claims about the novel coronavirus, which caused an outbreak in the central Chinese city of Wuhan before spreading elsewhere in the country and around the world.

Other social media users soon shared similar versions of the claim, referring to the investigation of two Chinese virologists in Canada in 2019. Kyle Bass, an American hedge fund manager who is currently shorting Hong Kong's currency, falsely claimed on Twitter that a "Chinese spy team" sent pathogens "to the Wuhan facility." He was retweeted 12,500 times, and screenshots of the tweet were shared on Facebook.

The claims appear to be based on a mischaracterization of August 2019 reports about a transfer of Ebola and Nipah viruses from a Canadian lab to Beijing, and an apparently separate issue involving two Chinese researchers at Canada's National Microbiology Laboratory (NML) in Winnipeg, in the central province of Manitoba.

The NML is part of the federal Public Health Agency of Canada (PHAC), whose senior media officer Tammy Jarbeau told AFP by email that "this is disinformation. (These) statements made on social networks have no factual basis."

The RCMP investigation

In July 2019, the Canadian Broadcasting Corporation (CBC) reportedthat two researchers with ties to China were removed from the NML in Winnipeg by the Royal Canadian Mounted Police (RCMP) for a possible "policy breach." The article did not mention the coronavirus.

Robert Cyrenne, spokesman for the RCMP in Manitoba, told AFP by email that "there is no connection between the outbreak in China and any RCMP investigation. Any reporting of such is misinformation."

Cyrenne confirmed to AFP that the investigation involving the researchers is still ongoing.

Dr Xiangguo Qiu, who helped develop a treatment for the Ebola virus, her husband Keding Cheng, a biologist who has published papers on coronavirus strains such as SARS-CoV, and Chinese students working under them had their security access revoked for Canada's only level-4 lab, a facility equipped for research on the deadliest diseases.

The virus transfer

Claims that the novel coronavirus was created in Canada refer to another report involving the NML. One month after Qiu, Cheng and the students were escorted off premises, CBC reported that live Ebola and Nipah viruses had been shipped to Beijing in March 2019 for research.

PHAC officials told CBC that all procedures were followed for the shipment of those level-4 pathogens, the deadliest. But the short interval between the Air Canada flight they were transported on and Qiu and Cheng's removal led to suspicion that the two events could be connected.

The RCMP declined to comment on any potential connection between the investigation and the virus shipment to Beijing.

Bass's tweet claims that Qiu was suspended for sending pathogens to Wuhan. In fact, the two pathogens were sent to Beijing, and were not coronaviruses.

The University of Manitoba, with which Qiu and Cheng were affiliated, has ended their non-salaried appointments and re-assigned the students working with them, a spokesperson told the Canadian Press.

Natural origin of virus

In a letter published on February 19, 2020 in The Lancet medical journal, a group of public health scientists made a statement about the origins of the novel coronavirus, which causes the COVID-19 disease. (https://www.thelancet.com/journals/lancet/article/PIIS0140-6736(20)30418-9/fulltext ... Note that one of the names is Peter

https://www.thelancet.com/action/showPdf?pii=S0140-6736%2820%2930418-9

"We stand together to strongly condemn conspiracy theories suggesting that COVID-19 does not have a natural origin. Scientists from multiple countries have published and analysed genomes of the causative agent, severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), and they overwhelmingly conclude that this coronavirus originated in wildlife, as have so many other emerging pathogens," they said.

A team of scientists led by Shan-Lu Liu of The Ohio State University also concluded that there is no "credible evidence" that the virus -- officially known as SARS-CoV-2 -- was engineered in a laboratory, in research published on February 26, 2020.

According to the Canadian government, as of March 24, 2020, there were 1,959 confirmed cases of novel coronavirus infection across the country. Twenty-seven people have died.

2020 (Feb 18) - "Statement in support of the scientists, public health professionals, and medical professionals of China combatting COVID-19"

PDF [HW002E][GDrive]

Statement in support of the scientists, public health professionals, and medical professionals of China combatting COVID-19

We are public health scientists who have closely followed the emergence of 2019 novel coronavirus disease (COVID-19) and are deeply concerned about its impact on global health and wellbeing. We have watched as the scientists, public health professionals, and medical professionals of China, in particular, have worked diligently and effectively to rapidly identify the pathogen behind this outbreak, put in place significant measures to reduce its impact, and share their results transparently with the global health community. This effort has been remarkable.

We sign this statement in solidarity with all scientists and health professionals in China who continue to save lives and protect global health during the challenge of the COVID-19 outbreak. We are all in this together, with our Chinese counterparts in the forefront, against this new viral threat.

The rapid, open, and transparent sharing of data on this outbreak is now being threatened by rumours and misinformation around its origins. We stand together to strongly condemn conspiracy theories suggesting that COVID-19 does not have a natural origin. Scientists from multiple countries have published and analysed genomes of the causative agent, severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2),[1] and they overwhelmingly conclude that this coronavirus originated in wildlife,[2–10] as have so many other emerging pathogens.[11,12] This is further supported by a letter from the presidents of the US National Academies of Science, Engineering, and Medicine[13] and by the scientific communities they represent. Conspiracy theories do nothing but create fear, rumours, and prejudice that jeopardise our global collaboration in the fight against this virus. We support the call from the Director-General of WHO to promote scientific evidence and unity over misinformation and conjecture.[14] We want you, the science and health professionals of China, to know that we stand with you in your fight against this virus.

We invite others to join us in supporting the scientists, public health professionals, and medical professionals of Wuhan and across China. Stand with our colleagues on the frontline!

We speak in one voice. To add your support for this statement, sign our letter online. LM is editor of ProMED-mail. We declare no competing interests.

Dr. Kent Brantly was 1st human given experimental treatment developed at National Microbiology Lab

CBC News · Posted: Apr 07, 2018 6:53 AM CT | Last Updated: April 9, 2018

A doctor who fought the Ebola outbreak in West Africa ended up being the successful guinea pig for an experimental treatment to fight the virus.

On Friday, he visited Winnipeg's National Microbiology Lab to thank the scientists who saved him, in person.

Dr. Kent Brantly, a family physician from Fort Worth, Texas, was part of the medical response to the Ebola outbreak in Liberia, where he was living and practising, in 2014. But while there, he contracted the deadly virus himself.

- **Dr. Kent Brantly, Ebola survivor, speaks of ending suffering in West Africa**
- **Ebola outbreak: Experimental treatment sparks who-you-know debate**

"I'm really glad to be able to meet you in person and tell you thank you," Brantly said to Dr. Gary Kobinger, a professor at the universities of Laval and Manitoba, who was involved in developing the treatment.

Brantly's recovery from what his doctors believed was death's doorstep was widely credited to the drug ZMapp, an antibody cocktail designed at Canada's National Microbiology Laboratory.

He reported feeling his fever break just 15 minutes after receiving the treatment.

"It's really a tremendous honour and privilege to meet him. I've seen your picture, I've watched interviews with you, but it is a great privilege to say thank you to someone who saved my life," Brantly said to Kobinger.

The treatment had never been used on a human being before, so when Brantly got sick, he was the first test subject.

- **Ebola 'cocktail' developed at Canadian and U.S. labs**
- **Ebola drugs can be tested on patients even if unproven, WHO says**
- **Canada offers experimental Ebola vaccine VSV-EBOV to West Africa**

"My story is just one of thousands," he said. But "through the attention that was given to my story, we saw a tremendous boost in support of the work that's required years and years in advance to have options available when an outbreak occurs."

Dr. Kent Brantly and Dr. Linda Mobula, assistant professor at John Hopkins School of Medicine and the physician who administered ZMapp to Dr. Brantly in Liberia. National Microbiology Lab scientists who created the Ebola treatment are also featured: Dr. Gary Kobinger, former chief of special pathogens, and Dr. Xiangguo Qiu, research scientist. (Submitted by Health Canada)

Kobinger, in return, thanked Brantly for his visit. He noted there was a huge team involved in both the treatment and in getting Brantly evacuated to a hospital in Atlanta, where he and another worker who had been exposed were treated.

"I would say that it's very humbling and very touching that he took the time to come and say thank you," Kobinger said.

Treating Brantly all happened so fast, he added.

"Despite the complexity of the environment, very important decisions can be made when people work together," he said. "Extraordinary achievements can be can be made also when we work together to resolve and solve problems and find solutions."

- **Post-Ebola Syndrome: Survivors continue to face mystery symptoms**
- **Ebola survivor from West Africa meets Winnipeg researchers who developed the drug that saved her life**

Before going to speak to a group at the University of Manitoba Friday, Brantly said he hopes what they take away from his visit is the importance of choosing compassion over fear.

"Choosing to do the right thing for your fellow human being rather than reacting out of fear and self preservation. That is not only true in my particular clinical story, but that's true of the work that happens in the lab every day — is setting aside the fear of working with deadly diseases to do good for others."

Brantly, who was the face of the Ebola fight on Time's 2014 Person of the Year cover, is speaking at a brunch Saturday morning at McDermot Avenue Baptist Church.

Born Gita Parekh 8 April 1956 , in Kampala, Uganda Protectorate

Died 31 March 2020 (aged 63) (Umhlanga, outside Durban, South Africa)

Nationality South African

Alma mater

University of Sunderland

University of KwaZulu-Natal

Known for

HIV research

Microbicides

Spouse(s)

Pravin Ramjee[1]

Scientific career

Fields Medicine, Pediatrics, HIV

Institutions South African Medical Research Council

Gita Ramjee FRCPE (née **Parekh**; 8 April 1956 – 31 March 2020) was a Ugandan-South African scientist and researcher in HIV prevention. In 2018, she was awarded the 'Outstanding Female Scientist' award from the European and Developing Countries Clinical Trials Partnership.[2] She died in Umhlanga, Durban, South Africa, from COVID-19 related complications.[3]

Early life and education

Gita Parekh was born on 8 April 1956[1][4] and grew up in Colonial Uganda before her family were driven into exile under Idi Amin in the 1970s.[4] She attended high school in India before attending the University of Sunderland in England. She graduated in 1980 with a BSc (Hons) in Chemistry and Physiology. She married a South African-Indian fellow student, Praveen Ramjee, and moved to Durban where she began working in the Department of Paediatrics at the Medical School of the University of KwaZulu-Natal. After her two sons were born she completed her Masters, and subsequently a PhD in 1994.[5]

Career

After completing her PhD in kidney diseases of childhood, Ramjee joined the South African Medical Research Council as a scientist.[5] She rose rapidly through the ranks to head the largest unit of the Council, the HIV Prevention Research Unit. She helped expand the unit from 22 scientific staff to 350 and was instrumental in growing its international reputation.[5]

At the time of her death, Ramjee was the Chief Scientific Officer at the Aurum Institute, a not-for-profit AIDS/Tuberculosis research organisation,[6] as well as director of the South African Medical Research Council's Prevention Research Unit. She received the Lifetime Achievement Award at the International Microbicide Conference in 2012. She was an honorary professor at the London School of Hygiene & Tropical Medicine, the University of Washington in Seattle, and the University of Cape Town.[6] She was a member of a number of local and international committees including the Academy of Science of South Africa (ASSAf) and the South African National AIDS Council (SANAC).[7]

Research

Her specialisation in HIV prevention and treatment research led her to lead the expansion of phase I through phase III HIV prevention and treatment clinical trials in the greater Durban area as the Clinical Trials Unit Principal Investigator.[7] Ramjee was concerned that the focus should not only be on clinical trials but treatment accompanied by HIV prevention education and care. In an interview she stated, "Women are the hardest hit by HIV in this region, and there is

still a lot to do to address health issues in developing countries. There is a need for [a] more holistic approach to HIV prevention which should include reproductive health care for women."[5] Ramjee was one of the first South African scientists to work on developing microbicides.[8]

She received the 2017 MRC Scientific Merit Award gold medal.[8]

As an academic, she published more than 170 articles and was both a reviewer and editor of several scientific journals.[7]

Death

Ramjee was in London to deliver a lecture at the London School of Hygiene & Tropical Medicine on 17 March 2020, entitled 'HIV: diverse challenges among children and women in Asia and Africa'. On her return to South Africa she felt unwell and was hospitalised. She died from complications relating to COVID-19.[6]

David Mabuza, deputy president of South Africa, led the tributes calling her a "champion in the fight against the HIV epidemic." As the chairperson of the South African National AIDS Council, he stated: "The passing of Professor Ramjee comes as a huge blow to the entirety of the healthcare sector and the global fight against HIV/AIDS."[9] Salim Abdool Karim, director of the Centre for the Aids Programme of Research in South Africa, praised her work for women, saying "She was involved in almost every major HIV prevention trial on microbicide … and defined her niche in developing technologies for women."[8] The president of the South African Medical Research Centre, Glenda Gray, also paid tribute to her work "She tried to address the whole ecosystem that makes women vulnerable, from the biological to the political."[8]

Professor Gita Ramjee, who recently returned from a trip to London, had been admitted to hospital with pneumonia. She was Chief Scientific Officer at the Aurum Institute and former chief specialist scientist and director of the South African Medical Research Council's (SAMRC) HIV Prevention Research Unit. She died in an Umhlanga hospital on Tuesday from Covid-19 related complications.

Professor Glenda Gray, president and CEO of the SAMRC, informed staff in an email of Ramjee's "tragic passing" due to "Covid-19 related complications".

The Aurum Institute said it was deeply saddened by the death of Ramjee whom they described as a "world-renowned scientist, who worked tirelessly to find HIV prevention solutions for women".

"The world has lost a bold and compassionate leader in the response to HIV," said Professor Gavin Churchyard, Group CEO of the Aurum Institute. "Gita Ramjee firmly believed in health as a fundamental human right. Her ground-breaking research in HIV prevention contributed to the global response to HIV and AIDS. Our thoughts during this difficult time are with her family, colleagues and the many people her life and work touched," he added.

Ramjee, recognised as a world-class scientist, spent her life focused on finding HIV prevention methods, which were conducive to the lifestyles, circumstances and perceived risk factors that South African women face. While at the SAMRC, Ramjee's KwaZulu-Natal based team was also at the forefront of attempts to find an effective HIV vaccine.

Ramjee held Honorary Professorships at the London School of Hygiene and Tropical Medicine, the University of Washington in Seattle and the University of Cape Town.

Ramjee was a critical player in the field of HIV prevention clinical trials and was acknowledged internationally for her expertise in the field of microbicide research, including a Lifetime Achievement Award for HIV Prevention. In 2018, she was honoured with the "Outstanding Female Scientist" Award by the European Development Clinical Trials Partnerships (EDCTP) for her life's work that has focused on finding new HIV prevention methods.

Ramjee has published more than 200 research articles. She was a reviewer and editor of several scientific journals and a member of several local and international committees and advisory groups including the Academy of Science of South Africa (ASSAf) and the South African National AIDS Council (SANAC).

"The Aurum Institute and the global HIV research community will mourn Gita Ramjee's passing and celebrate the huge contribution to the response to HIV she made in her life," said Churchyard.

Ramjee had been involved in the clinical trials of microbicides for over a decade. She collaborated with all the major sponsors involved in HIV prevention research, including UNAIDS, Population Council, the Bill and Melinda Gates Foundation, and the Wellcome Trust. **MC**

2007 (May 08) - (From The Guardian) Gita Ramjee: A passion for prevention

Source : [HM000R][GDrive]

The HIV researcher at the centre of a row over clinical trials tells Linda Nordling why she will never give up

Linda Nordling

Months have passed, but Professor Gita Ramjee still recoils at the memory of events that came close to robbing South Africa of one of its top scientists. "There came a point when I thought: is it worth my while? I have dedicated my life to finding an HIV prevention option for the women of Africa, and these recent attempts to tarnish my efforts have been very demotivating."

It is fitting that we meet on a day when freak waves and high winds are causing widespread damage along the Kwa-Zulu Natal coastline. A storm of a different kind rocked her research unit recently. A storm less forceful perhaps, but more damaging to those inside.

In January, Ramjee, director of the HIV prevention research unit in Durban, received the news that a routine inspection by an external team of experts had discovered anomalies in data from a study of a potential new microbicide to protect women against HIV/Aids. Alarmingly, more women receiving the vaginal preparation of cellulose sulphate appeared to have developed HIV, compared with the group not receiving the product. Although the numbers were very small, the external team decided to halt the trial for safety reasons.

A press release was issued explaining that the treatment "might" increase women's chances of HIV infection. Test products were recalled from the 1,333 women participating in South Africa, Benin, Uganda and India, and Conrad, the US-based sponsor of the trial, ordered a review to shed light on what had happened.

Press field day

Ramjee wished it could have stopped there. But it didn't. The press had a field day with what was incorrectly christened a "botched" trial. Some called the women testing the drug "guinea pigs", encouraged by the scientists to have unprotected sex using the gel as an aphrodisiac. "I think the whole world was horrified that certain South African press could stoop so low. That they could misunderstand an issue so much," says Ramjee

The articles were not just damaging to other HIV prevention efforts at the unit, but to clinical trials as a whole, she says. "Negative press such as this can destroy HIV prevention efforts. We need to have a united front, with civil society and scientists working together to address the problem and applauding volunteers who come forward to find solutions." But she admits her unit could have done more to prevent what happened. "In future, I would like to do it better, get the press involved, make them understand the science and interpretation of data."

In the aftermath, Ramjee received strong support from her colleagues, sponsors and even from participants in the trials. The last tried to put the record straight with the press. "Don't tell us that we are guinea pigs, we know exactly what we're doing, and can think for ourselves," they told the journalists. Did the press print their stories? "No."

But Ramjee's heart sank. It felt like the very people she had dedicated her life to help had turned against her. "At the time I was very, very depressed." But she did not give up. "A lot of people said to me: if you, one of the best clinical trialists in the world, don't continue with this fight against HIV/Aids, who will? So you have to motivate yourself again."

Such dedication to what she values most is a recurring phenomenon in Ramjee's life. Not for her the latte-sipping existence enjoyed by some of her contemporaries. "I'm not the type of woman who likes to spend hours at shopping centres with friends," she says. Instead, her life has revolved around her family and her career, with the former taking precedence.

Perhaps it was the many upheavals of her youth that taught her to hold on to what could always be counted on: close family and her own faculties. Growing up in Uganda, her first experience of exile came at the hands of Idi Amin, the dictator who forced all Asians out of the country in the 1970s. After a couple of years in a high school in India, the land of her ancestors, she relocated again, this time to the University of Sunderland in the north-east of England.

It was in here that she met her future husband - a South African of Indian descent. In 1981, on finishing her degree, she followed him to South Africa. It was a culture shock. In the early 80s the apartheid regime was weakening, but still held on to power, particularly in the Transvaal region, from where her husband's family came. "It was extremely difficult for somebody used to living in a multicultural, open society. As a student in England, you didn't look at colour. You looked at people as individuals."

In search of more liberal surroundings, the young couple moved to Durban. Here, Ramjee felt more at ease. She felt welcomed by people from a variety of backgrounds. "I think it was nice for them to meet somebody who wasn't thinking in the past. I felt very comfortable living in Durban at that time." She got a job in paediatrics at a local hospital. This put her in the way of a masters degree and, ultimately, a PhD on the kidney diseases of children, which she completed in 1994.

By that time she had two sons whom she tried - sometimes in vain - to shelter from the idiosyncrasies of South African society. "I was so determined, coming from a multicultural society, that I would never put my child in a single-race school." This was easier said than done, but in the end she succeeded.

The years of her doctorate saw Ramjee make superhuman efforts to stay on top of family and career. "I used to get up at six in the morning, prepare food, wake my children, send them off to school, do a half day of practical work, come back, pick my sons up from school, help them do their homework and send them to sleep." She would then herself go to sleep at 8pm only to get up again at two in the morning to write her thesis. She kept this up for a year. "I never gave up my responsibility as a parent. Although I wanted to excel in my career, I never wanted to compromise myself as a mother."

Nascent technology

The sacrifice paid off, but in a roundabout way. After her PhD, Ramjee wanted a break, but fearful of too much leisure time, she sought out a small project that would pass the time when her sons were at school. She found a small research project evaluating the acceptability of a vaginal microbicide, at that time a nascent technology in the armoury against HIV/Aids. This work put her in contact with local sex workers - a "reality check" as she calls it.

"It opened my eyes. These are good women, who are put in a position that people scorn." In the mid-90s, when Ramjee started working with sex workers in Kwa-Zulu Natal, 50% were HIV positive. "These women mostly aren't doing this out of choice. The stories they used to tell us were horrific. That's when I knew I wanted to be involved in the prevention of HIV infection in women."

What began as a short project evolved into a strong commitment. In the years to follow, Ramjee worked her way up through the ranks to finally head the Durban unit. She inherited a staff of 21, and quickly built this into a 300-strong organisation with an international reputation for excellence.

She is matter of fact about her success: "Because I did so well in clinical trials, I had offers pouring in for me to do clinical research. I think the key to success is my approach to capacity building, respecting each and every member of my staff, the community, and also the fact that I delivered on the contracts. It is my holistic approach to research, where I'm not just thinking science."

Today, Ramjee is looking ahead. The final results of a recently completed trial on a vaginal diaphragm will be out in the next couple of months and other trials are also nearing completion. There is a long way to go. "What people don't realise is that none of the current generation of microbicides or any other prevention technology is going to be 100% effective. So whether there are microbicides or a vaccine out there or not, there is nothing that will to allow you to go have unprotected sex without the risk of infection. Not for a long, long time."

Still, the recent crisis has taught her the importance of striking a new work-life balance. "In a way, I feel that while I'm passionate about my work, it is too consuming a passion. I need to find a more balanced situation, where I do things that I enjoy as well." But finding the time to do that will be difficult, she admits. "It's in my nature to want to excel. My calling is to find a solution. If I don't succeed in my lifetime, at least I've worked towards it."

Curriculum vitae

Age: 50

Job: Director of the HIV prevention research unit in Durban, South Africa

Lives: In Durban with her husband, a pharmacist

Likes: spas, exotic travels

UNIT NAME:

HIV PREVENTION RESEARCH UNIT

UNIT DIRECTOR: Gita Ramjee

STRATEGIC PURPOSE OF UNIT

The HIV Prevention Research Unit (HPRU) is one of the largest units of the South African Medical Research Council and is located in Durban, KwaZulu-Natal. The Unit is uniquely placed to address the HIV burden of disease in South Africa.

KwaZulu-Natal is also the epicentre of the global HIV epidemic leading to an enormous global and national interest to address the high HIV infection rates seen among men, women and adolescents in this region. HPRU is involved in cutting-edge research to address the HIV epidemic in sub-Saharan Africa as part of the global initiative to curb the epidemic.

2020 (April 1) - Global health clinical professor Gita Ramjee dies from COVID-19

source : [HE0027][GDrive]

By Jake Goldstein-Street and Ash Shah The Daily / Apr 1, 2020 Updated Apr 6, 2020

World-renowned HIV researcher Dr. Gita Ramjee, who was a clinical professor in the UW's global health department, has died from COVID-19 complications, the department announced April 1.

"Words cannot express our sorrow for the passing of Dr. Gita Ramjee," the department wrote in a tweet. She "was a wonderful colleague and friend who made major contributions to HIV prevention. @UW Global Health were fortunate to have her as clinical faculty."

Ramjee's death Tuesday, March 31, in a South African hospital was first reported by the BBC.

Ramjee was the chief scientific officer for HIV prevention for the Aurum Institute, a healthcare organization battling HIV.

"The world has lost a bold and compassionate leader in the response to HIV," professor Gavin Churchyard said in a statement from the Aurum Institute. "Gita Ramjee firmly believed in health as a fundamental human right."

Ramjee, who was a chief specialist scientist and director of the South African Medical Research Council's HIV Prevention Unit, received the Outstanding Female Scientist Award in 2018 from the European & Developing Countries Clinical Trials Partnership for her research on HIV prevention among women.

"I was absolutely thrilled by this award, as it recognizes decades of my commitment to clinical research activities in HIV prevention," Ramjee told the HIV Trials Network after receiving the award. "What makes it more rewarding is that I now stand among the female giants who received this award in the past."

The Microbicide Trials Network's Sharon Hillier and Jared Baeten, who is also vice dean of the UW School of Public Health, wrote of her passion for addressing gender disparities in HIV incidence, quoting a recent email from Ramjee reading, "It has been a long road with many ups and downs but we have forged along with strong determination."

She also held an honorary professorship from the London School of Hygiene and Tropical Medicine. UW spokesperson Victor Balta said in an email that Ramjee worked closely with many of the university's faculty and her title as a clinical professor was an honorary one.

A spokesperson for the department didn't think she taught courses on campus, but rather collaborated on HIV prevention programs with other faculty.

"She was always ready to share her extensive expertise and experience generously. We send our condolences to her family in this exceptionally difficult time," the global health department posted on its Facebook.

Ramjee appears to be the second UW faculty member to die from COVID-19 after a longtime member of the pathology department was claimed by the disease caused by the novel coronavirus in mid-March.

Four faculty and other academic personnel have now tested positive for the virus, as of April 1. That's on top of 17 staff members and 20 students for a total of 41 cases in the Seattle campus community. One UW Bothell staff member has also tested positive.

A UW campus custodian also died Tuesday, March 31, and was found to be positive for COVID-19, according to UW spokesperson Victor Balta. The employee's last day on campus was March 20.

Any staff members who came into close contact with this employee have been notified and asked to isolate until Apr. 3, 14 days after the individual's last day on campus, Balta said in an email.

"We are in contact with the employee's family and, out of respect for their privacy and time to grieve, we are not identifying the employee at this time," he wrote.

United States

Parent

Raytheon Company

The Raytheon Intelligence, Information and Services headquarters in Dulles, Virginia

Raytheon Intelligence, Information and Services (**RIIS** or **IIS**) is a business unit of Raytheon Company headquartered in Dulles, Virginia.[1] IIS specializes in intelligence, surveillance and reconnaissance; advanced cybersecurity solutions[buzzword]; weather and environmental solutions[buzzword], and information-based solutions[buzzword] for homeland security. The company also provides training, logistics, engineering, product support, and operational support services and solutions[buzzword] for the mission support, homeland security, space, civil aviation, counter-proliferation and counter-terrorism markets.[2] IIS employs approximately 17,000 people at 551 sites in 100+ countries worldwide. In 2018, the company recorded $6.7 billion in sales and $538 million in operating income.[3] Dave Wajsgras is the President of IIS.[4]

History

In 1995, Raytheon Company acquired E-Systems, Inc. *[See **E-Systems, Incorporated**]* , a Texas-based company that designed, developed, produced and serviced high technology systems including surveillance, verification, and aircraft ground-land navigation equipment. The company also developed electronics programs and systems for business, industrial, and non-defense government programs and agencies.[6] E-Systems was renamed Raytheon Intelligence and Information Systems.

In 2013, Raytheon Company announced the consolidation of its six internal business units to four.[7] Intelligence and Information Systems was combined with Raytheon Technical Services Company and renamed Raytheon Intelligence, Information and Services.

Technologies and capabilities

- Data & Network Security[8]
- Big data Analytics, Processing and Dissemination[9]

- Big data Analytics, Processing and Dissemination[9]
- Command and Control of Air and Space Vehicles[10]
- Geospatial Intelligence (GEOINT)
- Automation and Machine Learning
- Signal and Image Processing
- Air Traffic Management Solutions[11]
- Mission Systems Integration[12]
- Training & Knowledge Management[13]
- Operations, Maintenance and Engineering[14]
- Logistics & Product Support[15]

Organization

Raytheon Intelligence, Information and Services is organized into five business units, known internally as Mission Areas:

Cybersecurity and Special Missions (CSM)

The Cybersecurity and Special Missions (CSM) mission area provides end-to-end cyber capabilities that address data and network security threats to governments and critical infrastructure. CSM provides customers with computer network defense, advanced persistent threat protection, and cyber hardening of military systems and critical infrastructure. In addition to advanced technologies, CSM develops integrated systems, tradecraft and support capabilities for a broad spectrum of special missions.

CSM Fast Facts

- In the last ten years, Raytheon has invested $3.6 billion to develop and acquire cyber capabilities[16]
- IIS develops self-healing technologies that can automatically detect and fix cyber vulnerabilities[17]
- Raytheon's CODE Center is a "cyber range" used to test and harden systems and system-of-systems[18]
- Raytheon's end-to-end CND capabilities include managed security services (MSS)[19] and virtual security operations centers (V-SOC) [20]
- Raytheon conducts 500 million+ vulnerability tests per week[*citation needed*]

Global Intelligence Solutions (GIS)

The Global Intelligence Solutions (GIS) mission area develops and integrates large-scale, high-performance signals intelligence (SIGINT,) geospatial intelligence (GEOINT) and Multi-INT systems. GIS provides commercial and intelligence customers with large-scale information processing, integration and visualization systems for intelligence, satellite and space-based programs. It also supports national security objectives by providing comprehensive technical, analytical and operational support to the intelligence community.

GIS Fast Facts

- Raytheon systems handle metadata tagging and sharing of up to 40,000 interagency transactions per second
- GIS employees and systems process 60 percent of all strategic intelligence missions
- 100 percent of Proforma collection from National Technical Means is performed by Raytheon

Global Training Solutions (GTS)

[...] The Global Training Solutions (GTS) mission area helps customers in high-consequence environments leverage training expertise and the latest technologies to align tailored learning and asset life-cycle solutions[*buzzword*] to their mission objectives. GTS solutions[*buzzword*] increase trainee proficiency, improve ROI and reduce costs for customers in defense and military organizations, civil agencies and commercial industries including healthcare, finance, oil & gas, and automotive.

GTS Fast Facts

- Raytheon trains personnel in 127 countries and 29 languages[13]
- Raytheon and General Motors are partnering to train U.S soldiers for civilian jobs as auto technicians[21]
- Since 2008, Raytheon has trained almost every deploying US Army soldier[22]

Mission Support and Modernization (MSM)

The Mission Support and Modernization (MSM) mission area provides full life-cycle mission operations, engineering, sustainment and modernization services for site and platform missions, as well as multi-intelligence (Multi-INT) ground systems, multi-domain command and control systems, commercial software integration, border security and unmanned systems technology.

MSM Fast Facts

- MSM is using modern, commercial software methods to develop new command and control applications for the U.S. Air Force[23]
- Raytheon is modernizing the Army's Distributed Common Ground System, replacing the existing mobile intelligence platform with a version that allows deployed soldiers to quickly collect and analyze intelligence data[24]
- The North American Aerospace Defense Command (NORAD) Cheyenne Mountain Complex is maintained and operated by Raytheon[25]
- Raytheon maintains and modernizes systems for NASA's Neutral Buoyancy Laboratory (NBL), a super-sized pool used to simulate microgravity conditions in space[26]
- NASA's Earth Observing System Data and Information System (EOSDIS), the world's largest repository of environmental data, was developed and is maintained by Raytheon[27]
- In partnership with the US Army, Raytheon is developing videogame-based virtual reality training technology[28]

Navigation, Weather and Services (NWS)

The Navigation, Weather and Services (NWS) mission area provides satellite-based mission planning and data processing to support civil and military missions, specializing in the ground systems needed to launch, operate and plan satellite missions. NWS also provides modernized air traffic management with a focus on cyber-hardened avionics, GPS-guided precision landing, and enhanced weather planning. NWS is building the control segment that will operate the next generation of Global Positioning System (GPS) satellites, known as GPS OCX.[29][30] It also provides environmental solutions for defense, civil, commercial and international customers.

NWS Fast Facts

- Raytheon systems supply 90% of space-based earth observation data used to generate two- to ten-day worldwide weather forecasts[31]
- The NWS team developed, operates and sustains primary National Weather Service forecasting tools at more than 120 offices in the U.S., Guam and Puerto Rico[32]
- NWS supports the U.S. Air Force's effort to modernize America's GPS enterprise[33]
- Raytheon technology and support provides safe transportation for more than two-thirds of the world's airspace[34]
- NWS develops satellite-based navigation systems that allow pilots to perform precision landings on any runway[35]
- Raytheon operates more than 360 tolling points across the globe and was a pioneer of electronic open road tolling[36]
- Raytheon operates the command and control systems of the James Webb Space Telescope[37]

Locations

Raytheon Intelligence, Information and Services operates out of several major locations in the US, including:

- Dulles, Virginia - Corporate Headquarters
- Richardson, Texas
- Aurora, Colorado
- Orlando, Florida
- Indianapolis, Indiana
- Linthicum, Maryland
- Riverdale Park, Maryland
- Omaha, Nebraska
- State College, Pennsylvania
- Burlington, Massachusetts

Former presidents

- David Wajsgras (2015-2020)[4]
- Lynn Dugle (2009-2015)[4]
- Mike Keebaugh (2002-2009)[38]

[HE0021]

William C. Reeves

Professor of Epidemiology, Emeritus

Berkeley

1916-2004

William Carlisle Reeves died of a cerebral hemorrhage, subsequent to a fall, on September 19, 2004. He was 87 years old. Though officially retired in 1987 from the University of California, Berkeley, he continued to serve actively until shortly before his death: advising students, presenting occasional lectures and seminars, participating in research, and consulting with federal state and local public health agencies. He vigorously took part in a departmental faculty meeting on the day of his fall, just four days before his death. Reeves' former student, now chief of epidemiology at the Arbovirus Disease Branch of the Centers for Disease Control and Prevention (CDC), Roy Campbell, described him as, "…a giant in the field of arbovirology. When he talks, people listen". Indeed, Bill Reeves was the preeminent pioneer and expert on the causes and transmission of mosquito-borne viral encephalitides in the world. In fact, he invented the term arbovirus to describe these arthropod-borne (transmitted) diseases.

Reeves grew up on a ranch outside Riverside, California, the only child of William Claude Reeves and Abie Bessie Harriet Brant. His father kept bees, but Bill did not attribute his lifelong interest in "bugs" to his father's vocation. In fact, he seems to have had an aversion to bees. However, he did get his lifelong interest in fishing and hunting from his father, who took him on month-long trips into the California mountains after the "honey harvest" was over in late summer. His interest in entomology was encouraged and guided by his junior high school biology teacher. His friends and schoolmates dubbed him "Billy Bugs," an appellation he seems to have savored. Although neither of his parents had been educated beyond grammar school, they were determined that their son would get a college education.

Reeves began his college career at Riverside Junior College. More importantly, during two summers he worked at the Citrus Experiment Station of the Riverside campus of the University of California. There he came in contact with dedicated research scientists and graduate students from the University of California, Los Angeles. So, after completing the junior college program at Riverside, he moved on to Berkeley, which had the best undergraduate and graduate program in entomology in the west. In a bizarre incident when Reeves was well into his thesis research on the treehole mosquito, investigators in another institution learned about a key finding by Reeves. When they incorporated this information into their research, it led to prior publication by them. Reeves was, therefore, forced to begin his research again, and building on his previous work, he moved his project to the Hooper Foundation at the University of California, San Francisco. There he came under the tutelage and direction of the world-renowned virologist K. F. Meyer and there also he began his collaboration with virologist/epidemiologist William M. Hammon. When an epidemic of Western Equine (WEE) and St. Louis Virus (SLE) encephalitis occurred in Yakima County, Washington in 1941, Meyer dispatched a team under Hammon's direction to investigate. Reeves played a major role in the investigation that resulted in the first isolation of viruses (WEE and SLE) from naturally infected mosquitoes (*Culex tarsalis*). The resulting publications and Reeves's thesis are classics. With these accomplishments, at age 26, Reeves's career was launched.

Reeves got his master of public health (M.P.H.) degree from the School of Public Health at Berkeley in 1949. He was one of the first graduates from the newly established school, a school which was created due to the efforts of people like K. F. Meyer and William M. Harmon. Even while pursuing the M.P.H., Reeves was lecturing on epidemiology. He was, in large part, responsible for the growth and development of the epidemiology program at Berkeley, now one of the preeminent academic epidemiology programs in the country.

Bill Reeves's scientific accomplishments were substantial. He identified several previously unidentified viral agents of disease and new species of arthropod vectors. His research was always "goal oriented". That is, he was concerned with the potential his findings would have with regard to disease prevention. And, though his investigations took him as far afield as Guam and the Murray Valley in Australia, his focus was always on the Central Valley of California. Nor was his research ever "esoteric". He was always sensitive to practical issues of methodology. Thus, he devised the first mosquito "live trap", invented a tracking method by marking mosquitoes with a fluorescent dye, and innovated the "sentinel chicken" monitoring system that has become a prime component of arbovirus surveillance worldwide.

Reeves was active in all the relevant professional organizations, governmental and nongovernmental. He received many prestigious awards, among them the UC Berkeley Distinguished Teaching Award, the Berkeley Citation, the John Snow Award from the American Public Health Association, a U.S. Army Medal for Distinguished Civilian Service, and the Walter Reed Medal from the American Society of Tropical Medicine and Hygiene.

He was an outstanding teacher both in the classroom and as an advisor of students engaged in doctoral research. Bill was a tough taskmaster, concerned with the smallest details, but stimulating and sensitive. He chose his doctoral students carefully and many now hold important positions in academia and governmental agencies around the world. He served on Berkeley's Graduate Council and as dean of the School of Public Health from 1967 until 1972.

With the appearance of West Nile Virus encephalitis in 1999, Reeves resumed an active role in planning research and control strategies for the disease, even though he had retired in 1987. He served as a member of the California West Nile Virus Steering Committee and as a participant in the CDC's weekly "conference call" to concerned agencies regarding the status and planning for the control of the epidemic. One of the regular participants in the weekly conference call remarked: "…The groundbreaking research that Bill and his colleagues did on the SLE virus – a close cousin to West Nile virus – gave us a roadmap for understanding West Nile virus, helping us to predict how it would behave in North America…".

When Bill Reeves was 12 years old he had a job delivering the *Saturday Evening Post*. One of his customers, a Mr. Moultin, resisted paying for the magazine, necessitating collection from his wife or daughter. That daughter, Mary Jane, later became Mrs. William C. Reeves. They had three sons; William C., Robert, and Terry.

Bill took great pride in his special California automobile license plate number: **"Culex T"**!

A medical entomologist and leading figure in arbovirology. **He was born on Dec 2, 1916**, in Riverside, California, USA, and died aged 87 years from complications following a fall on Sept 19, 2004, at John Muir Medical Center in Walnut Creek, California.

On a Sunday afternoon some 35 years ago, William (Bill) Reeves was sitting in the back yard of his colleague Leonard Syme's house, chatting about work over a barbecue. Syme's 8-year-old son, David, was nearby, listening to the grown-ups talk. Reeves asked him, "Do you know what my job is?" "Sure", said David. "You're a psychologist who's interested in mosquitoes." In retrospect, Len Syme—now professor emeritus of epidemiology at the University of California, Berkeley—thinks his son somehow got it right. Although Reeves' scientific legacy is as a pre-eminent arbovirologist, those who knew him also recall a man whose gruff exterior hid a sensitive and insightful heart.

Together with William M Hammon, Reeves led a research team that in 1941 isolated both western equine and St Louis encephalitis viruses from the *Culex tarsalis* mosquito. Their work confirmed for the first time that the diseases, which had plagued the western USA throughout the 1930s, were transmitted by insects. He also invented the "sentinel chicken" disease-monitoring system, when he discovered that chickens develop antibodies after being bitten by infected mosquitoes, but do not become ill or carry enough virus to transmit the disease. The system was adopted by California's Encephalitis Surveillance Programme and has since been copied worldwide. It is still used today in some areas to monitor the spread of West Nile virus.

Reeves grew up on his family's farm in Riverside, California, and inherited a love of the outdoors from his father. His fascination with insects surfaced early. "My interest even led to a nickname in the rural neighbourhood of 'Billy Bugs Reeves', which didn't bother me any", he told the UC Berkeley Regional Oral History office in a 1990 interview. He went on to earn a bachelor's degree in entomology from Berkeley in 1938, and a doctorate in medical entomology and parasitology in 1943. During World War II, Reeves worked as a civilian adviser to the US military, investigating mosquito-borne viruses, including a 1945 outbreak of Japanese encephalitis in Okinawa. After the war, in 1949, he earned a master's in epidemiology.

Until his retirement in 1987, Reeves was a professor of epidemiology at Berkeley, and served as dean of its School of Public Health from 1967 to 1971. He never moved far from the Californian university, nor did his academic attention shift far from *Cx tarsalis*. "He was a giant in the field of arbovirology", said Roy Campbell, a graduate student of Reeves who now heads the surveillance and epidemiology activity of the Arboviral Diseases Branch at the US Centers for Disease Control and Prevention, in Fort Collins, Colorado. "But he was also extremely knowledgeable in the history of public health." His academic stature was matched by his imposing, six-foot-plus physique. "He reminded us all of John Wayne", said Campbell, and like Wayne's motion-picture cowboys, he could be taciturn, brusque, even rude.

"He would sometimes characterise people in a way that could be rude, but then a year later it would turn out to be exactly right", said Syme, a sociologist who Reeves hired at the school of epidemiology in the late 1960s. "Over the years, every time I would go to him for advice, I'd get 10 or 15 minutes of abuse about what I needed to fix and so on, but then he would switch gears and come up with the most sensitive, intuitive, reasonable advice ever."

After his retirement, Reeves came to the UC Berkeley campus 4 days a week, and continued teaching a few graduate students. "He was very direct. In an intellectual environment, you had to be on your toes", said Campbell. "But he was an extremely good academic advisor, and was respectful of his graduate students, giving each one a great deal of attention."

In 1999, when West Nile Virus emerged as a public-health threat, first in New York, and then further afield in the USA, health officials asked Reeves for his advice. "He was contacted very early on when the birds started to fall out of the sky", said Campbell. Already in his 80s, Reeves participated in conference calls that the CDC held during the virus transmission season, and his research on St Louis encephalitis provided a blueprint for understanding West Nile and predicting its behaviour. "It was all stuff Bill and his colleagues had described 40 years ago", Campbell said.

Reeves is survived by his wife Mary Jane; sons William Jr, Robert, and Terrence; four grandchildren; and a great-granddaughter.

Atom Tests At Martin's

By WILLIAM B. HARWOOD

THERE'S a swimming pool at the Martin Company, but none of the aircraft firm's employés would think of using it.

For at the bottom of this inviting-looking pool is enough radioactive cobalt to kill a man.

The Martin Gamma Facility, as the pool is formally called, was designed for two purposes: (1) to test the effect of radiation on various substances, and (2) to provide Martin engineers and scientists with a fund of research information.

Although there are about fifteen such pools in the country—at such places as the Argonne National Laboratories, the Naval Research Laboratory, Oak Ridge and Brookhaven—Martin claims one of the first built by private industry, with private capital, for the exclusive use of industry.

Clear View To Bottom

Physically, the gamma facility is simple in appearance. The pool, flush with the floor but protected by a concrete curb and a waist-high iron railing, is a 6-by-6-foot square, 12 feet in depth and filled with water.

The still, blue-green water not only provides shielding for the radioactive source but it permits a clear view to the bottom of the tile pool. There, a 13-inch pipe, 2½ inches in diameter, protrudes from the center of a stainless-steel disk, about one yard in diameter. It looks like a huge turntable from an oversized record player.

Two removable iron grates stretched across the top of the pool permit technicians to stand directly above the radioactive source while lowering or raising samples by means of overhead pulleys and cranes.

The pipe protruding from the disk in the floor of the pool is an aluminum-clad cylinder of cobalt-60, the radioactive metallic element artificially produced by bombarding cobalt in its natural state (cobalt-59) with neutrons.

Circled With Cobalt Rods

Samples of test-tube size can be lowered into the core of the pipe in an aluminum cylinder.

Larger samples, pieces of equipment or other items may be placed around the pipe on the stainless-steel disk. They can be surrounded with cobalt rods in various patterns depending upon the amount of radiation desired.

The cobalt source in the central pipe alone consists of 1,500 curies of cobalt-60 (a curie being a unit of measure equal to 37,000,000,000 disintegrations per second) which emit 470,000 roentgens per hour. By adding cobalt rods around the perimeter of the disk, which increases the curies to 4,500, the radiation flux can be stepped up to between 500,000 and 800,000 roentgens per hour, depending upon the exact location of the sample being irradiated.

Test Effect On Materials

An idea of the amount of gamma ray dosage present in the pool was given by Harry Garabedian, chemist in charge of the facility. An exposure of 400 roentgens to the entire human body would be lethal to 50 per cent of the population, he explained. There is more than 100 times that lethal dosage emitted in the Martin pool every hour.

But the twelve feet of water over the radiocobalt provides biological shielding with a considerable margin of safety and, at the same time, allows complete visibility.

Housed In Lead Shield

In the past, Martin has had to confine its radiation research to cobalt-60 of about 800 curies activity, which is housed in a lead shield, called a pig, 20 inches in diameter. Nothing larger than test-tube samples could be tested in the pig, however.

With the manufacture of airplanes on the verge of nuclear propulsion, it is necessary to find out the amount of shielding required for an airborne reactor and the effect of radiation on near-by materials in the body of the plane.

For example, Martin has announced the organization of a team of engineers to push development of a nuclear-powered jet seaplane. The company had been working for three years on a Navy-sponsored program of engineering studies seeking an airframe for such a craft. And company officials admit the nuclear propulsion research program had "matured to the point" where the engineering team was set up from necessity.

Many Substances Tested

Martin made no reference to a nuclear-power plant for its P6M, huge four-jet engine SeaMaster seaplane which has been described by Secretary of the Navy Charles S. Thomas as an aircraft which may be capable of future atomic flight.

In its new swimming pool, however, Martin can submerge the entire sonar system from a P6M and test the effect of gamma radiation it would receive from a near-by nuclear reactor. Martin officials have no comment on such use of the pool. It has many other uses they do talk about, however.

Martin is testing the effect of radiation on lubricants, metals, plastics, woods and other substances.

Not only is it important to know the amount of radiation various materials will withstand—without changing their basic properties—but Martin engineers are equally interested in finding out exactly what structural change will take place when a given material is irradiated.

Split Into Two Sections

Consequently, the Radiation Effects Group, headed by Dr. Jerome Morse, is divided into two sections.

One is devoted to Martin's "moderator program" and has as its principal aim the finding of an organic moderator to replace water as the energy regulator and heat transferant in a nuclear reactor. This section also is devoted to "pure basic research" and development of a fund of information without regard to product application. Martin engineers feel their company is unusual in this respect.

On the other hand, Dr. Alfred J. Restaino, lead engineer in the plastics research program, is almost solely concerned with product application.

He has been working extensively on "graft coplymerization"—a process of combining by radiation two different materials to produce a third which contains the properties of both.

New Combinations Found

So far, Dr. Restaino and his staff have come up with fifteen new combinations, some quite startling which they are not ready to talk about.

In one unclassified case, for example, they took a well-known commercial insulating material which has exceptionally high resistance to heat but poor adhesive qualities. To this material, they added vinyl acetate which is used in the adhesive industry. It can tolerate little heat. Irradiation of the two materials produced a new substance which is both highly adhesive and able to withstand high temperatures.

Application of such a discovery to Martin's product is obvious. Not only does the company manufacture airplanes and rockets which fly at speeds greater than that of sound, it is building the three-stage rocket which it hopes will take the first earth satellite some 300 miles into upper space next year.

In such work, the need is basic for materials which can withstand the tremendous heats and pressures generated at the speeds and altitudes to be explored.

Limitations Of Water

Martin also has its own nuclear reactor program and has already developed a nuclear-packaged power plant which is portable to any part of the world.

That reactor, as do most, uses water to slow down the neutrons and moderate the energy and heat being produced. But water has its limitations. It corrodes metal, therefore shortening the life of reactor parts. It boils at 212 degrees Fahrenheit. It must be purified highly before it can be run through the reactor.

So Martin is looking for an organic moderator to replace water. Through the new gamma facility, it hopes to find one. The moderator sought must do double duty—slow down the neutrons sufficiently and at the same time carry off the heat. The compound must be able to withstand high temperatures and at the same time bear up under the stress of radiation.

Plastic Possibilities

Some of the plastics offer possibilities. They are more viscous, or syrupy, than water. Their boiling point is higher.

But can they withstand the stress of radiation? When exposed to radiation will their structure change? And if it changes, will it break down or cross link, becoming stronger?

These are some of the questions for which Martin engineers seek solutions. In some cases they already have found the answers. Through use of the new gamma facility, they hope to find many more.

Cutaway drawing of the Martin Gamma Facility where effect of radiation on various substances is tested. Water in pool shields scientists from deadly radioactivity yet permits clear view of bottom. Box on wall at right is meter which constantly records amount of radiation present in room and sounds warning if level becomes dangerously high.

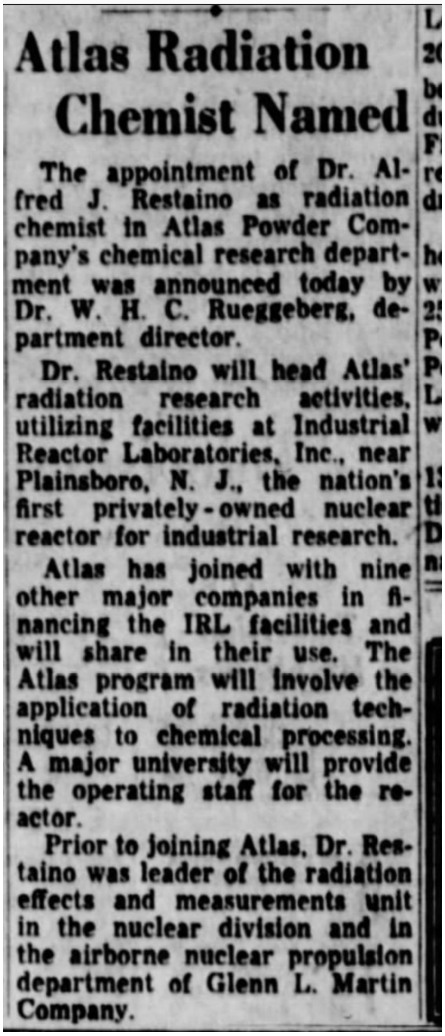
The News Journal (Wilmington, Delaware) • 17 Mar 1958



Atlas Radiation Chemist Named

The appointment of Dr. Alfred J. Restaino as radiation chemist in Atlas Powder Company's chemical research department was announced today by Dr. W. H. C. Rueggeberg, department director.

Dr. Restaino will head Atlas' radiation research activities, utilizing facilities at Industrial Reactor Laboratories, Inc., near Plainsboro, N. J., the nation's first privately-owned nuclear reactor for industrial research.

Atlas has joined with nine other major companies in financing the IRL facilities and will share in their use. The Atlas program will involve the application of radiation techniques to chemical processing. A major university will provide the operating staff for the reactor.

Prior to joining Atlas, Dr. Restaino was leader of the radiation effects and measurements unit in the nuclear division and in the airborne nuclear propulsion department of Glenn L. Martin Company.

Engineers Week Speakers To Address 4 Service Clubs

Martin S. Blackman

Dr. Alfred J. Restaino

Edward M. Doyle

Engineers representing the Du Pont Company, Atlas Powder Company and Thiokol Chemical Corporation will help suburban service clubs observe National Engineers Week at dinner meetings tomorrow evening.

The Wilmington North Kiwanis Club, meeting at 6:30 in the Holiday Inn, will hear Martin S. Blackman, a project engineer in the propellant projects section of Thiokol's Elkton division. His topic will be "Solid Propellant Rocketry."

The Brandywine Hundred Lions Club, meeting at Fabian's on the Philadelphia Pike, will hear Edward M. Doyle, also of Thiokol in Elkton, on the same subject.

The New Castle Rotary Club, meeting at 6:30 in the Arsenal-on-the-Green Tea Room, will hear Dr. Alfred J. Restaino of Atlas' industrial reactor laboratories in Plainsboro, N. J., on "Radiation and the Age of Space."

The Kiwanis Club of Red Clay Valley, meeting at 6:30 in the Powder Mill, will hear Dr. John J. Cox of the Du Pont Experimental Station on "A New Engineer for the Space Age."

Blackman is concerned with the improvement of propulsion systems for air-to-air missiles. His talk will cover the history of rocketry, the composition of solid propellants, the application of solid propellants to past, present and future missile systems, and the organization of Thiokol. He has been associated with the Navaho missile while at North American Aviation.

Doyle has been engineering test suervisor for rocket engine development projects under Air Force contracts with Curtiss-Wright; propulsion engineer with the Glenn L. Martin Company for the Navy "Viking" missile, and project engineer on "Falcon" program with the Redstone Division of Thiokol in 1953. He has been head of the projects department at Elkton since December 1956.

Restaino was appointed research associate at Brooklyn Polytechnic Institute in 1955, under an Atomic Energy Commission contract with Brookhaven National Laboratories. He taught chemistry and physics as an adjunct professor at St. Francis College and physics as an adjunct professor in the Graduate School at Drexel Institute. He was supervisor of the radiation effects units in the airborne nuclear propulsion department at Glenn L. Martin Company of Baltimore. In 1958, he joined Atlas and is now supervisor of its radiation research.

Author of eight publications on radiation chemistry, he was recently co-author of a book, "Effects of Radiation on Materials."

John D. Brandner

Alfred J. Restaino

Brandner to head unit at Atlas

Atlas Chemical Industries, Inc., has reorganized its chemical research department, naming Dr. John D. Brandner department director and appointing Dr. Alfred J. Restaino assistant director.

The move is being made to prepare for future managerial needs, accordig to Edward J. Goett, Atlas president.

Since 1961, Brandner has been associate director of chemical research. He joined Atlas in 1934 as a chemist. He received his Ph.D. in chemistry from Columbia University. From 1956 to 1961, he was manager of the physical, chemical and analytical section of the research department.

1970-07-17-the-morning-news-wilmington-de-pg-42-clip-atlas

RESTAINO, who will be responsible for the research groups in organic, polymer, radiation and new product applications, developed the new Atlasep flocculant series recently announced by Atlas for use in water purification.

Joining Atlas in 1958 after obtaining a physical chemistry doctorate from Polytechnic Institute of Brooklyn, Restaino moved up to become manager of the polymer section in the research department in January 1968.

In other department shifts, Dr. Frederic R. Benson, manager of information services, will assume responsibility for the technical library, patent liaison and research information. Dr. Paul Becher has been named manager of the department's physical chemistry section.

MOVED to supervisory positions as heads of eight laboratory groups were: Dr. Leon W. Wright, supervisor of the catalysis and physical measurement group, physical chemistry section; Dr. Leland F. Gleysteen, supervisor of the surface chemistry group, physical chemistry section; Dr. Stanley J. Jankowski, supervisor of the instrumental aalysis group, analytical section; and, in the same section, Dr. Frank P. Wetterau, supervisor of the general analysis group.

Chemical industry looks eagerly to Detroit

Plastics shape up as the backbone of the future car, from radiators to fenders to pistons. Companies like Du Pont are reacting.

By TERRY BIVENS
Staff reporter

In a scene from the movie "The Graduate," the parents of a young man fresh from college in the East are throwing a cocktail party in his honor at their southern California home.

The graduate, played by Dustin Hoffman, is almost catatonic as he contemplates his "future." Standing awkwardly on the fringes of the party, he is approached by a business friend of his parents.

The man wraps his arm around Hoffman, riveting him with a meaningful look, and says he wants Hoffman to think about one word:

"Plastics."

Although plastics elicited nothing more than a hilarious blank stare from Hoffman, similar scenes are probably being re-enacted today at parties in posh Detroit suburbs like Bloomfield Hills and Grosse Point.

Merely substitute a chemical manufacturer for the businessman and an automaker for the anxious young man. And skip the laughter, because plastics and fibers — in ways far beyond the traditional uses as seat covers and upholstery — are shaping up as a major new, multimillion-dollar market for the chemical suppliers of the automotive industry.

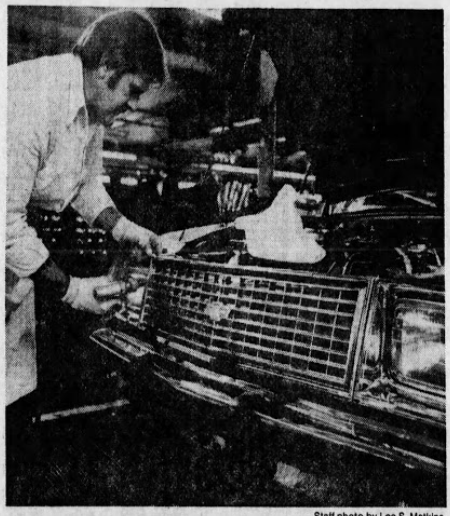
From radiator tanks to valve covers, from windows to fenders, from hoods and body panels to pistons, plastics may become the backbone of the car of the future.

"We see it as a major new opportunity," says Terrance N. Cressy, a spokesman for Du Pont Co.'s automotive market development offices in Detroit. "Almost every chemical company that produces plastics is looking at Detroit with a new eye."

Like most trends in the U.S. automotive industry, the push for new plastic parts is a reaction to the sharp increases in oil prices since the 1973 Arab oil embargo and fierce competition from smaller, more fuel-efficient foreign models.

By substituting plastics for heavier metal parts, U.S. automakers find they can reduce auto weights and increase fuel efficiency. Plastic parts, in many cases, can be made cheaper; and many of them can withstand the temperatures in today's smaller, hotter-running engines.

Chemical companies — Du Pont, Hercules Inc., ICI Americas Inc., Monsanto, Dow, Union Carbide, Allied and the oil companies' chemical subsidiaries, among others — are only too happy to oblige. New-product lines are an excellent hedge against sales declines that resulted from the recent slump in auto sales and a "downsizing" trend that has reduced the dimensions of existing products.



Staff photo by Leo S. Matkins

On the assembly line at General Motors' Boxwood Road plant, Thomas Radzius installs a plastic grille on a Chevette

Already the proportion of plastic in the modern American car has increased. According to Irvin E. Poston, a spokesman for General Motors Corp. in New York, plastic currently accounts for about 6 percent — roughly 200 pounds — of the weight of an average GM auto.

By the mid-1980s, Poston says, that portion may go as high as 10 percent. And because improving technology may result in lighter plastics, that percentage could be conservative since there could be more plastic to the pound.

"The potential is there for some really big new-product lines," Poston says.

Some chemical industry analysts, however, react cautiously to the new development. Like Hoffman's graduate, they say, the auto industry must be convinced.

"Detroit is going through some bad times," says Emily Plishner, a securities analyst for Oppenheimer & Co. in New York. "Since they are down, they must be persuaded that they are really looking at something good — and not something that will prove expensive to them.

"Right now, I think we're in a stage where the chemical companies are looking to present their ideas. And the company that presents the best idea first may come up with the big market share."

"Remember, the auto market only accounts for about 10 percent of chemical-industry sales," says Sano Shimoda, an analyst for the First Boston Corp. in New York. "I think the real question will be which plastics they will focus on."

Most chemical companies are purposefully vague about the direction of their development program for the auto industry. As R. Byron Pipes, an associate professor of mechanical and aerospace engineering at the University of Delaware and a Du Pont Co. consultant, points out:

"They are all after the same business, only from different perspectives. They don't really want their competitors to know where they are putting their dollars."

As a firm that once was the controlling stockholder in General Motors, Du Pont can obviously be expected to be a leader in developing new auto products. The company is already the leading chemical-products supplier to the auto industry, with worldwide auto-related sales last year of $1.5 billion.

"Du Pont is looking for every conceivable use," said Ms. Plishner. "I'm sure they think their market for new auto products will expand and become one of their fastest-growing areas."

According to Cressy, Du Pont has a virtual armada of new products that could double unit volume in a plastics division that accounted for $2.8 billion of sales last year.

The company is developing reinforced fibers and plastics for such under-the-hood applications as valve covers, mounting brackets and radiators. Acrylics are already in use on bus windows, and could replace glass on cars. There are new plastic bumper guards, steering columns, electronic parts, metal-reinforcing fibers for body parts, power window gears and emission-control components.

"We're looking at a really big material switch-over," says Cressy. "Plastics are joining steel as a primary material for the automotive industry."

At Hercules, the emphasis is on polypropylene, a lightweight, inexpensive plastic and fiber. Hercules is the world's largest producer of

See CHEMICAL — D-5

Chemical firms look to Detroit

Continued from D-1

polypropylene, with about 25 percent of the market capacity.

"Detroit is extremely receptive now to plastic applications," says A.D. "Jack" Veale, Hercules' product director for plastics. "And when they think of plastics, they think of polypropylene."

Polypropylene, Veale says, has excellent temperature resistance, which makes it promising for engine parts. Also, Hercules has major plans for body parts made of a "sandwich" of polypropylene and steel.

Veale said about 14 percent of Hercules' polypropylene sales goes to the automotive industry.

"We've about saturated the uses in the car compartment," he says. "Right now, the car exteriors are the big thing. We think it will be a dramatic growth area."

Hercules is also working on automotive uses for its graphite fibers, a light, strong material that could be used for engine and transmission brackets, bumpers and hoods.

However, the price of graphite fibers — which now sell for about $10 a pound for million-pound orders — may still be too much for Detroit.

"That may take awhile because the fiber is still expensive," says Ms. Plishner. "The company is using the fibers in military aircraft, but the consumer car is a different story."

ICI Americas, whose parent company, Imperial Chemical Industries Ltd. of London, is a major supplier of finished products for European automakers, is concentrating on polymer plastics that can be molded into bumpers and other body parts.

"At present we're supplying the basic chemicals that later turn up in cars," said Alfred J. Restaino, director of the company's corporate research department in Wilmington. "We're hoping to get into the auto business, especially with the hard plastics. But right now, it represents a big opportunity, but a difficult one."

Human guinea pigs: the trend in testing drugs

By Jane Harriman
Staff reporter

The woman had suffered from incapacitating, seemingly incurable anxiety for years.

That began to change when, as a volunteer for a research project, she was able to test a drug not yet approved by the U.S. Food and Drug Administration. The drug was so effective, she was able to obtain a "compassionate use" permit, allowing her to continue taking the new medicine and complete her recovery.

The test "turned her life around," said Dr. Catherine M. Clary, a Wilmington psychiatrist who headed the project for the Private Practice Research Group.

Private Practice is part of a growing trend: private groups that test drugs, using human volunteers as guinea pigs.

While most research of this kind is done in university hospitals with their abundant supply of clinic patients, it is quickly expanding to private offices whose patients are likely to be more representative of the population as a whole, and of the market drug companies want to reach.

That's especially true in the area of psychiatry; patients at university hospital clinics tend to suffer from more chronic forms of mental illness. Because many of them are poor, they may also have additional health problems — making drug testing even more complicated.

Private Practice is one of two private groups in Delaware conducting clinical trials for anxiety drugs. Hypertension Services of Wilmington is the other.

Soon to join them is the Medical Research Institute of Delaware, a public/private cooperative venture between the state, the Medical Center of Delaware, the Du Pont Co. and ICI Americas Inc.

See HUMAN — E3

Human guinea pigs: the trend in testing drugs

• Continued from E 1

The institute is being started with a $500,000 one-time grant from the state, and $250,000 each from Du Pont and ICI. The Medical Center is donating 6,000 square feet of space.

Eventually, the institute will be supported by the companies whose drugs it tests.

The Governor's High Technology Task Force recommended establishing the institute, which will test medicines on healthy subjects who are paid for their participation.

Dr. Alfred Restaino, executive director of the task force, said the purpose behind this initial, "safety" phase is to determine how a healthy body reacts to a particular drug.

On the other hand, both Clary's group and the Hypertension group, headed by nephrologist Dr. William E. Miller, work with volunteers who have the disease or symptoms. This is known as Phase II and Phase III testing.

In Phase II, drugs are tried on a relatively small group.

In Phase III — the final stage before FDA approval — a much larger group participates, usually at testing centers around the country.

Volunteers in Phase II and Phase III do not have to pay for the medication, or for the close medical attention they get during the trial.

They do have to be diligent about following instructions and reporting to the research center for required examinations and laboratory tests.

Clary said participants in her studies have an initial telephone interview of 10 to 15 minutes, followed by a complete physical and mental evaluation.

If they meet criteria for the trial and wish to participate, they then must report to the office once a week for half an hour.

The process is confidential. Participants are not identified by name — but by a numerical code.

Clary said researchers do not know until the study is over which drug a participant used.

That's to keep the process as objective as possible — a real concern since drug companies pay for the research.

Furthermore, the drug companies don't in any way reward researchers whose findings are encouraging.

Dr. Alfred J. Restaino

Of **Wilmington, DE** died November 19, 2002 of ALS (Lou Gehrig's disease.

Dr. Restaino was born in Brooklyn, NY February 18, 1931 to the late Clement and Cecilia Orlando Restaino. He received his BS degree magna cum laude from St. Francis College of New York, and his MS and PhD in physical and polymer chemistry from Brooklyn Polytech Institute, now New York Polytechnic University. He credits his 2 close friends and mentors, Stephen A. Fauci and Dr. Donald Metz as having a significant impact on his life and career.

At his 1980 retirement, he was director of corporate research and development for ICI Americas. Dr. Restaino was credited with over 150 publications and 50 patents. Some of his patents became successful commercial products in oil recovery, water pollution and high performance plastic resins and polymers. During the 1960s, he served as a member of the Atomic Energy Commission. Dr. Restaino served as the executive director of the office of Science and Technology to Governor Mike Castle and was instrumental in seed funding for the Center for Composites Material Research at the University of Delaware, where he also served as adjunct professor of physical chemistry in the 1970s.

He is survived by his wife of almost 50 years, Raffaela B. Sessa Restaino; 4 sons, Stephen, Alfred, Peter and Mario; and 1 daughter, Lisa Restaino Flaherty; their spouses; 13 grandchildren; and 3 brothers, Fred, Neil and Clem.

A viewing will be held from 6-9 pm on Thursday, November 21 at the MCCRERY MEMORIAL FUNERAL HOME, 3924 Concord Pike, Wilmington. A Mass of Christian Burial will be offered at 10:30 on Friday, November 22 at St. Mary Magdalen Catholic Church, Concord Pike & Sharpley Rd., Wilmington. Interment will be in St. Joseph's on the Brandywine Cemetery, Wilmington.

Condolences may be sent to www.mccreryfuneralhome.com

Ferederick Restaino

RESTAINO

FREDERICK A., PhD

Age 83, retired Senior Director of Pharmaceutical Research & Development for Merck, passed away peacefully at his home on June 17, 2018, surrounded by his family. Devoted husband of 60 years to Camille (nee Giordano). Loving father to Fred Restaino (Eileen), Debbie Giovannone (John) and Denise Magill (Dave). Dear brother to Neil Restaino (Marie) and the late Alfred and Clement Restaino, also survived by 7 grand-children and one late grand-child. Relatives and friends are invited to his viewing Thursday, 9:30 A.M. until 10:45 A.M. at St. Alphonsus Church, 33 Conwell Dr., Maple Glen, followed by Funeral Mass 11:00 A.M. In lieu of flowers, memorial contributions can be made to Fox Chase Cancer Center (www.FoxChase.org).

Obituary for Frederick A. Restaino

https://obittree.com/obituary/us/pennsylvania/philadelphia/louis-a-digiacomo-funeral-home/frederick-restaino/3536552/index.php

FREDERICK A. RESTAINO, PhD, devoted husband, brother, loving father, and proud grandfather passed away peacefully in his home in Maple Glen, PA, on June 17, 2018, at the age of 83. He had spent 60 wonderful years with his soulmate --his "treasure" – Camille (nee Giordano), with whom he raised three beloved children, Fred Restaino (Eileen), Debbie Giovannone (John), and Denise Magill (Dave), and cherished grandchildren, John (Gen), Nicholas (Taylor), Charlie, Alaina, Ryan, David, and Kathryn. He was a dear brother to Neil (Marie) the late Alfred (Rae) and the late Clement (Rose), and an especially close brother-in-law to Marie Colasante (Richard) and Pat Giordano (Stella). He deeply loved all of his nieces, nephews, and great niece and great nephews.

Frederick, "Fred," was born in Brooklyn, New York, son of the late Clement and the late Celia (nee Orlando) Restaino. Though he raised his family in Horsham and later Maple Glen, PA, he never truly left behind his New York roots and remained a devout Yankees fan his whole life. He attended St. John's Preparatory High School and on June 29, 1958 married Camille, the love of his life, with whom he was inseparable for the next 60 years. A lifelong academic, Fred was a proud alumnus of St. John's College of Pharmacy in New York City; Rutgers University, where he obtained a Master of Science in Pharmaceutical Chemistry; and Purdue University, where he earned a PhD in Physical Pharmacy. He harbored a great love for research science and went on to work 34 fondly remembered years at Merck in West Point, PA, where he served as Senior Director of Research and Development for 13 years and made many lifelong friends. Few topics of conversation could light up his face like his time at Merck, with the important exception of his family, which always remained his one true joy.

Those who met Fred even for a short time will remember him as a man of great warmth, generosity, integrity, and faith. He enjoyed life's simple pleasures, including watching Wheel of Fortune every night, working on jigsaw puzzles, and above all, spending time with his family.

Family and friends of Fred are invited to attend his viewing Thursday, June 21, 2018, from 9:30am until 10:30am, followed by his funeral mass 11:00am at St. Alphonsus Church (33 Cornwell Drive, Maple Glen PA 19002), where Fred was a devout parishioner for over 30 years. His interment will be in St. John Neumann Cemetery, Chalfont, PA. In lieu of flowers, memorial contributions can be made to Fox Chase Cancer Center, 333 Cottman Ave., Phila., PA 19111 or www.FoxChase.org. Share memories at www.DiGiacomoFuneralHome.com.

Frederick Alfred Restaino Edit Profile

pharmacist

Frederick Alfred Restaino, American pharmacist. Achievements include patent in field. Member Rho Pi Xi, Rho Chi.

Background

Restaino, Frederick Alfred was born on December 9, 1934 in Brooklyn. Son of Clement and Cecilia (Orlando) Restaino.

Education

Bachelor of Science in Pharmacy, St. John's University, 1956. Master of Science in Pharmaceutical Chemistry, Rutgers University, 1959. Doctor of Philosophy in Physical Pharmacy, Purdue University, 1962.

Career

Senior research pharmacist, Merck, Sharp & Dohme, West Point, Pennsylvania, 1961-1966; research fellow, Merck, Sharp & Dohme, West Point, Pennsylvania, 1966-1972; senior research fellow, Merck, Sharp & Dohme, West Point, Pennsylvania, 1972-1982; director pharmaceutical development, Merck, Sharp & Dohme, West Point, Pennsylvania, 1982-1995.

Achievements

- Frederick Alfred Restaino has been listed as a noteworthy Pharmacist by Marquis Who's Who.

Membership

Member Rho Pi Xi, Rho Chi.

Connections

Married Camille M. Giordano, June 29, 1958. Children: Frederick J., Deborah Ann, Denise Marie.

Cornelius Packard "Dusty" Rhoads (June 9, 1898 – August 13, 1959) was an American pathologist, oncologist, and hospital administrator who was involved in a racism and unethical human experimentation scandal and subsequent whitewashing in the 1930s. Beginning in 1940, he served as director of Memorial Hospital for Cancer Research in New York, from 1945 was the first director of Sloan-Kettering Institute, and the first director of the combined Memorial Sloan–Kettering Cancer Center. For his contributions to cancer research, Rhoads was featured on the cover of the June 27, 1949 issue of Time magazine under the title "Cancer Fighter".[1]

During his early years with the Rockefeller Institute in the 1930s, Rhoads specialized in anemia and leukemia, working for six months in Puerto Rico in 1932 as part of the Rockefeller Foundation International Health Board contingent. During World War II, he worked for the United States Army helping to develop chemical weapons and set up research centers. Research on mustard gas led to developments for its use in chemotherapy at Sloan Kettering.

In early 1932, a letter Rhoads had written in November 1931, which disparaged Puerto Ricans and makes claims (which he referred to later as jokes) he had intentionally injected cancer cells into his patients, was given by a lab assistant to Puerto Rican nationalist leader Pedro Albizu Campos. He publicized the letter in the Puerto Rican and American media, which led to a scandal, an official investigation,[2] and a US whitewashing campaign to protect Rhoads and, by extension, Rockefeller interests.[3] In the ensuing investigation, Rhoads defended himself, saying he had written his comments in anger and as a joke to a New York colleague.[4] Neither Puerto Rico's Attorney General nor the medical community found evidence of his or the project's giving any inappropriate medical treatment, and the scandal was forgotten.[5][6]

In 2002, the controversy was revived. Alerted to the incident, American Association for Cancer Research (AACR), which had established the Cornelius P. Rhoads Memorial Award in 1979,[7] commissioned a new investigation.[8] It was led by Jay Katz, emeritus professor at Yale Law School and a specialist in medical ethics. He concluded there was no evidence of unethical human experimentation, but the letter was so offensive that the prize should be renamed. AACR concurred and stripped the honor from Rhoads because of his racism.[6]

Early life and education

Rhoads was born June 20, 1898, in Springfield, Massachusetts, as the son of an ophthalmologist, Dr. George H. Rhoads, and his wife.[9] He received his early education in Springfield, later attending Bowdoin College in Maine, where he graduated in 1920. He entered Harvard Medical School, where he became class president, and in 1924, he received his M.D., cum laude.[9] Rhoads became an intern at Peter Bent Brigham Hospital, and contracted pulmonary tuberculosis. During his treatment and recovery, he developed a lifelong interest in disease research.

Early career

After recovering from TB, Rhoads published a paper on the tuberculin reaction with Fred W. Stewart, who became his longtime colleague. Rhoads taught as a pathologist at Harvard and conducted research on disease processes.[10]

In 1929 Rhoads joined the staff of the Rockefeller Institute for Medical Research, now Rockefeller University, where he worked for [**Dr. Simon Flexner (born 1863)**]. He was also staff pathologist at Rockefeller Hospital.[11] His early research interests included hematology and poliomyelitis. He worked at Rockefeller until 1939.[12][13]

Puerto Rico

While working for the Rockefeller Institute, in 1931 Rhoads was invited by hematologist William B. Castle to join his Rockefeller Anemia Commission, to conduct clinical research at Presbyterian Hospital in San Juan, Puerto Rico.[11] This was part of the Rockefeller Foundation's sanitary commission on the island through the International Health Division.[14] Castle's research interest was pernicious iron deficiency anemia, specifically as caused by the parasitic hookworm, which was endemic on the island at rates of 80%, and tropical sprue.[3][6][11] An effective treatment for the latter had just been developed, although the disease's causes remained obscure.[11] As recently as 2010, medical journal Nieto Editores reported that these conditions continued to cause high mortality in Puerto Ricans.[15] The cause of tropical sprue has still not been identified, but since the 1940s, it can be treated with folic acid and a 3 to 6-month course of antibiotics.[16]

Rhoads was to assist Castle, and they established a base in San Juan at the Presbyterian Hospital. Rhoads corresponded often with Simon Flexner at the Rockefeller Institute in New York regarding his research and career interests. In Puerto Rico, the Rockefeller group had more than 200 patients; historian and ethicist Susan E. Lederer notes that, while referred to as patients, they were primarily clinical subjects whose conditions were studied to advance medical research. Because of the effects of anemia and the suspicion that tropical sprue was related to diet, Rhoads experimentally controlled patients' diets.[11] Lederer notes that in letters from this time, Rhoads referred to his patients as "experimental 'animals'." [11] He wrote: "If they don't develop something they certainly have the constitutions of oxen." Rhoads sought to experimentally induce the conditions he was studying in his patients rather than simply treat them. If they did develop tropical sprue, he could treat it with liver extract.[11]

Castle wanted to perform a similar study in Cidra, in conjunction with the School of Tropical Medicine, which was doing related research, but this was not approved. Rhoads also collected polio serum samples for his boss Flexner at the Rockefeller Institute, for which he was assisted by contacts at the university.

Scandal

On 10 November 1931, Rhoads was at a party at a Puerto Rican co-worker's house in Cidra. After having some drinks, he left, and found that his car had been vandalized and several items stolen. He went to his office, where he wrote and signed a letter addressed to "Ferdie" (Fred W. Stewart, a colleague from Boston, by then working at the Memorial Hospital for Cancer Research in New York).[11]

He wrote the following:

Dear Ferdie:

The more I think about the Larry Smith appointment the more disgusted I get. Have you heard any reason advanced for it? It certainly is odd that a man out with the entire Boston group, fired by Wallach, and as far as I know, absolutely devoid of any scientific reputation should be given the place. There is something wrong somewhere with our point of view.

The situation is settled in Boston. Parker and Nye are to run the laboratory together and either Kenneth or MacMahon to be assistant; the chief to stay on. As far as I can see, the chances of my getting a job in the next ten years are absolutely nil. One is certainly not encouraged to make scientific advances, when it is a handicap rather than an aid to advancement. I can get a damn fine job here and am tempted to take it. It would be ideal except for the Porto Ricans. They are beyond doubt the dirtiest, laziest, most degenerate and thievish race of men ever inhabiting this sphere. It makes you sick to inhabit the same island with them. They are even lower than Italians. What the island needs is not public health work but a tidal wave or something to totally exterminate the population. It might then be livable. I have done my best to further the process of extermination by killing off 8 and transplanting cancer into several more. The latter has not resulted in any fatalities so far... The matter of consideration for the patients' welfare plays no role here — in fact all physicians take delight in the abuse and torture of the unfortunate subjects.

Do let me know if you hear any more news.

Sincerely, "Dusty"[17][18]

His unmailed letter was found by one of his staff and circulated among workers at the Anemia Commission. When Rhoads learned of this, he quickly made a public apology at a meeting of all staff and doctors.[11] A while later, he was dismayed to hear that the letter was going to be discussed at a meeting of the Puerto Rico Medical Association. With relations having deteriorated locally, he returned to New York in December 1931.[11]

Publicity and investigations

Pedro Albizu Campos

At the end of December, Rhoads' former lab technician Luis Baldoni resigned; he later testified that he feared for his safety. In January 1932 he gave the Rhoads letter to Pedro Albizu Campos, president of the Puerto Rican Nationalist Party.[11] Albizu Campos sought publicity about the incident, sending copies of the letter to the League of Nations, the Pan American Union, the American Civil Liberties Union, newspapers, embassies, and the Vatican.[2]

In addition to distributing the letter to the media, Albizu wrote his own, charging that Rhoads was part of a US plot to exterminate Puerto Ricans. He linked the letter to other complaints about American imperialism, saying that the US governors in Puerto Rico encouraged labor emigration rather than improving employment, and promoted birth control, which was offensive to the majority Catholic residents.[17] Later that year Governor Beverley struggled with a greater political crisis than the Rhoads letter over his own remarks encouraging birth control use on the island. Residents were outraged and he was removed from office.[17]

A photograph of the Rhoads' letter was published on January 27, 1932 in La Democracia, the Unionist newspaper of Antonio Rafael Barceló, with a translation in Spanish of the entire letter. It did not support Albizu Campos' theory of a US conspiracy against Puerto Rico. On February 13, El Mundo published the entire letter, in both Spanish and English.[17]

The Rhoads' letter created one of the first crises for James R. Beverley, newly appointed as the acting Governor of Puerto Rico. He said the letter was a "confession of murder" and "a libel against the people of Puerto Rico", and ordered an investigation, one of his first acts.[17] Beverley said of Rhoads that "he was just a damned fool, ... a good doctor, but not very strong mentally on anything else."[17] Rhoads, already back in New York, released an official response to the media and the governor. He insisted that he was joking in his letter, which was intended to be confidential, calling it a "fantastic and playful composition written entirely for my own diversion and intended as a parody on supposed attitudes of some American minds in Porto Rico," explaining that nothing "was ever intended to mean other than the opposite of what was stated."[2] Rhoads offered to return to clear things up, but never did. The governor's inquiry concluded that Rhoads did not commit the acts included in his letter, nor any other crimes.[2]

Rhoads and his work were investigated by the Puerto Rican Attorney General Ramon Quinones, with review of medical aspects by Dr. P. Morales Otero, representative of the Puerto Rico Medical Association, and Dr. E. Garrido Morales, representing the Commissioner of Health. Sworn testimony was taken from several of Rhoads' patients as well as his colleagues, including Castle, William Galbreath, and George C. Payne. They reviewed the case files for the 257 patients treated by Rhoads and the Rockefeller Commission, including the 13 patients who died during this period. They found no evidence of the crimes described in Rhoads' unmailed letter. The Attorney General and medical community joined in absolving Rhoads of the Nationalist charges that he was part of a U.S. plot to exterminate Puerto Ricans.[5] Rhoads was subject to separate investigations ordered by the acting American governor of Puerto Rico, Beverley, and the Rockefeller Institute, and "neither...was able to uncover any evidence that Dr. Rhoads had exterminated any Puerto Ricans."[8]

Confirmed in Lederer's 21st century account, "records at Presbyterian Hospital in San Juan, Puerto Rico, where Rhoads had performed his research, revealed no patients in the young pathologist's care had died under suspicious circumstances."[4][11] Additionally, the investigators were "unable to confirm Rhoads's other claim (omitted in Time 's account) that he had 'transplanted cancer into several patients.'"[4][19]

During the investigations, Ivy Lee, who handled public relations for the Rockefeller family, and a team at the Institute began a campaign to defend Rhoads' reputation. He was seen as a promising researcher. The Rockefeller Foundation also wanted to protect its working relationship with medical organizations in Puerto Rico[11] and avoid problems with critics of human experimentation in the U.S. During the early 1930s, there was a revival of the anti-vivisectionist movement in the U.S., which also was concerned about the use of vulnerable populations as human subjects of experimentation: children (especially orphans), prisoners, and soldiers. As Lederer observed, "some members of the medical community...monitored the popular and medical press."[20] [**Dr. Francis Peyton Rous (born 1879)**] of the Rockefeller Institute was editor of the Journal of Experimental Medicine through the 1930s and 1940s. Although it accepted few articles on clinical research, he was careful about their wording in an effort to avoid criticism by the anti-vivisectionists.[21]

Lee was given access to pre-published versions of the articles on the controversy by both The New York Times and Time. He persuaded Time to eliminate the words "and transplanting cancer into several more," from its published version of the letter.[3] Also, based on the positive testimony of some patients, The New York Times headlined its article as "Patients Say Rhoads Saved Their Lives" and reported on this aspect as well.[22] Rhoads had returned to New York before the scandal broke in Puerto Rico. After the Attorney General's report[5] and that of the Rockefeller Institute in 1932, the controversy quickly faded in the United States.[11][23]

Reaction to the Rhoads scandal and controversy was mixed in the United States, in part due to the Rockefeller campaign. Starr says (in his 2003 article on the scandal) that Rhoads' colleagues did not believe the researcher's attempt to cast his letter as a "fantastic and playful composition...intended as a

parody."[2] Some were worried about Rhoads' mental health at the time. A superior dismissed the incident as a case of local ingratitude. Time magazine headlined the incident as "Porto Ricochet"; Starr suggests they meant that Rhoads's humanitarian work in Puerto Rico had come back to bite him.[2]

In Puerto Rico, Albizu Campos used the Rhoads scandal as part of his anti-colonial campaign, attracting followers to the Nationalist Party. In 1950, longtime Puerto Rican pro-independence activists Oscar Collazo and Griselio Torresola tried to assassinate President Truman to bring their cause to the world stage. When later interviewed, Collazo said that as a young man, in 1932 he heard Albizu Campos speak about the Rhoads letter and decided to devote his life to the Nationalist movement.[8][11][23]

Hematology

Following his study in Puerto Rico, in 1933 Rhoads was chosen to lead a special service at the Rockefeller Institute in clinical hematology, to study diseases of the blood-forming organs. He built on his research on anemia and tropical sprue.[24] In 1934 Rhoads and another researcher published results of the success in using liver extract therapy to treat tropical sprue (and relieve anemia).[25] Their work was recognized as contributing benefit in treatment of the disease by others in the field.[26]

Memorial Hospital and World War II

In 1940, Rhoads was selected as director of Memorial Hospital, which was devoted to cancer care and research, and had recently moved into a new building. Rhoads was selected for his interest in clinical investigation in addition to laboratory research, as the hospital did research as well as treatment.[27] He succeeded James Ewing, a noted oncologist. Ewing had written about cancer transplantation in 1931, a subject which Rhoads had referred to in his scandalous letter written in November of that year.[11] In 1941 Rhoads was studying the use of radiation to treat leukemia.[28]

During World War II, Rhoads was commissioned as a colonel and assigned as chief of medicine in the Chemical Weapons Division of the U.S. Army.[27] He established the U.S. Army chemical weapons laboratories in Utah, Maryland, and Panama. With his enthusiastic participation, secret experiments including race-based tests involving African Americans, Japanese Americans, and Puerto Ricans were performed on more than 60,000 U.S. soldiers. Many were left suffering from debilitating, lifelong aftereffects.[29] For this work, he won the Legion of Merit for "combating poison gas and other advances in chemical warfare" in 1945.[7][29]

Due to his casualty studies on mustard gas from an accident during the war in Italy, Rhoads became interested in its potential for cancer treatment. For the rest of his life, his research interest was in developing chemotherapy for cancer treatment,[27] but he served primarily as an administrator and scientific director at Memorial and Sloan-Kettering. From studies of mustard gas, he developed a drug called mechlorethamine or Mustargen. Its success in clinical trials during the war years was the basis for the development of the field of anti-cancer chemotherapy.[30] Rhoads also became interested in total body irradiation, which led to early work on chemotherapy.[31]

Post-war

In 1945 Sloan-Kettering Institute was founded as a cancer research center, in the hopes that an industrial approach to research would yield a cure.[27] It opened in 1948. While still director of Memorial, from 1945 until 1953 Rhoads also served as the first director of the Sloan-Kettering Institute.[8][27] He was "praised by Memorial for his 'essential role in the evolution of the hospital into a modern medical center.'"[8][27] **As director of Sloan-Kettering, he had oversight as well over research related to Department of Defense radiation experiments through 1954. For instance, that year, a Sloan-Kettering team began a multi-year study of "Post-Irradiation Syndrome in Humans."**[32]

In 1953, Rhoads stepped back slightly, becoming scientific director of the newly merged Memorial Sloan–Kettering Cancer Center.[27] He also continued as the scientific director of Sloan-Kettering operations.[33] He also was an adviser to the United States Atomic Energy Commission regarding nuclear medicine. Some AEC funding supported Sloan-Kettering research into the use of iodine to transport radiation to cancer tumors.[34]

Rhoads continued to serve as scientific director of the Memorial Sloan–Kettering Cancer Center until his death.[33] He died of a coronary occlusion on August 13, 1959, in Stonington, Connecticut.[10] [He was only 61 yers of age]... In 1979, on the 20th anniversary of his death, the American Association for Cancer Research established the Cornelius P. Rhoads Memorial Prize in his honor, as an annual award to a promising young researcher.[7]

Honors

- Legion of Merit in 1945 for Rhoads' work for the US Army during WWII.[7]
- Trustee of the Charles Kettering Foundation.[27]
- Awarded three honorary doctorates, two for science and one for law.[27]
- Posthumously awarded the Katherine Berkin Judd Award for outstanding contributions to oncology research.[10]
- The American Association for Cancer Research (AACR) established the Cornelius P. Rhoads Memorial Award posthumously in his honor in 1979.[7](In 2002, it renamed the award due to Rhoads' racism expressed in his 1932 letter.)[8]

Revival of controversy

In 1982, Puerto Rican social scientist and writer Pedro Aponte-Vázquez discovered new information at various archives which raised questions about the investigations conducted on Rhoads and Rockefeller Project. Most prominent among his findings was a 1932 letter written by Governor Beverly to the associate director of the Rockefeller Foundation, stating that Rhoads had written a second letter "even worse than the first" and which, according to Beverley, the [Puerto Rican] government had suppressed and destroyed.[23] In 1932 the Puerto Rican Attorney General, aided by top-ranking Puerto Rican doctors, had investigated all of the work of Rhoads and the Rockefeller Project, including 13 deaths that occurred among nearly 300 patients treated. They found no evidence of wrongdoing or crimes.[5] In addition, Rhoads' superior at the Rockefeller Project had conducted a close investigation of the 13 patients who died under Rhoads' tenure, but found no evidence of wrongdoing. But in 1982 Aponte-Vázquez urged the Puerto Rico Department of Justice to reopen the case. It refused as Rhoads had been dead for so long.[23]

In 2002, Edwin Vazquez, a biology professor at the University of Puerto Rico, came across Rhoads' 1932 letter and contacted the American Association for Cancer Research (AACR) about it. Given the letter's offensive nature, he demanded that Rhoads' name be removed from the AACR award. Others also contacted the AACR, including Puerto Rico's Secretary of State Ferdinand Mercado.[35] Revival of the issue generated a fresh wave of publicity. The AACR, which said it had not known of the 1932 controversy,[8] commissioned an investigation led by Jay Katz, a bioethicist from Yale University. Katz said although "there was no evidence of Dr. Rhoads' killing patients or transplanting cancer cells, the letter itself was reprehensible enough to remove his name from the

award." The AACR agreed with his conclusion.[8]

Eric Rosenthal of Oncology Times in 2003 characterized the case as the AACR having to "deal with the embarrassment of having history catch up to modern-day sensibilities."[8] He wrote,

The complicated legacy of Cornelius "Dusty" Rhoads, who died in 1959, should not cause society to promote nor deny his existence but should provide a perspective that neither condones what he wrote or thought—or the whitewashing of the incident by institutions and media of the 1930s—but that does give him due appropriate credit for his accomplishments as well as acknowledgement of his faults and sins."[8]

In 2003 the AACR renamed the award, stripping the honor from Rhoads posthumously. The AACR indicated that the new name would be retroactive and past awardees would receive updated plaques.[8][36]

Representation in other media

- Aponte-Vázquez self-published a book in 2005 entitled The Unsolved Case of Dr. Cornelius P. Rhoads: An Indictment; he writes on this topic via his blog and personal website.
- During the 1980s, the Puerto Rican political satire comedy group, Los Rayos Gamma, performed parodies of Rhoads with Jacobo Morales portraying a Cornelio Rodas as an insane, Frankenstein-like scientist bent on the elimination of Puerto Ricans.[37]
- Roberto Busó-García wrote and directed the dramatic film, The Condemned (2013), which he said was loosely based on the Rhoads' controversy in Puerto Rico.[38]

Nonconsensual testing on humans Southam, Rhoads (boss of Dr. Chester Southam), (Dr. Alice Moore also, but not mentioned)

[HB006B][GDrive]

I used to believe that the “cancer conspiracy” was an unintentional result of the love of money and that there were really no malicious intentions at its roots. However, due to stories like the three that follow, I believe that I was a bit naïve in my initial assessment of the situation.

In 1931, [**Dr. Cornelius Packard "Dusty" Rhoads (born 1898)**], a pathologist from the Rockefeller Institute for Medical Research, purposely infected human test subjects in Puerto Rico with cancer cells, and thirteen of them died. Despite the fact that Rhoads gave a written testimony stating he believed all Puerto Ricans should be killed, **he later established the U.S. Army Biological Warfare facilities in Maryland, Utah and Panama, and was named to the U.S. Atomic Energy Commission, where he began a series of radiation exposure experiments on American soldiers and civilian hospital patients**.

Then, in **1963, []Dr. Chester Milton Southam (born 1919)**] (who injected Ohio State Prison inmates with live cancer cells in 1952) performed the same procedure on twenty-two senile, African-American female patients at the Brooklyn Jewish Chronic Disease Hospital in order to watch their immunological response. He told the patients that they were receiving “some cells,” but conveniently left out the fact that they were cancer cells. Ironically, Southam eventually became president of the American Association for Cancer Research!

In 1981, the **Seattle-based Genetic Systems Corporation** began an ongoing medical experiment called “Protocol No. 126” in which cancer patients at the **Fred Hutchinson Cancer Research Center** in Seattle were given bone marrow transplants that contained eight experimental proteins made by Genetic Systems, rather than standard bone marrow transplants. As a result, 19 human “subjects” died from complications directly related to the experimental treatment. Inhibition of Development of Sarcoma 180 by 4-Amino-N[10]-Methyl Pteroylglutamic Acid.*

ALICE E. MOORE, C. CHESTER STOCK, K. SUGIURA, AND C. P. RHOADS.

From the Division of Experimental Chemotherapy, Sloan-Kettering Institute for Cancer Research, New York City.

In view of the extensive developments among the anti-metabolites it was a natural consequence that cancer chemotherapy studies should be initiated with analogs of folic acid. Interest in the folic acid antagonists has been stimulated by reports of the effectiveness of Aminopterin in the treatment of leukemia (Farber).[1] In an intensive screening program during the past year a large number of analogs of folic acid and various related simple compounds have been studied against mouse leukemia[2] and various mouse and rat tumors with particular emphasis on the Crocker mouse Sarcoma 180. Thus far, one folic acid antagonist,[3] 4-Amino-N[10]-methyl pteroylglutamic acid (A-Methopterin),† has been outstanding in its ability to inhibit the growth of Sarcoma 180. The preliminary results of the study are presented.

Materials and methods. The material was tested for ability to inhibit the growth of the Sarcoma 180 and also for its ability to damage a well established tumor.

Carefully selected tumors were cut into 2 mm cubes and implanted subcutaneously into the axillary region of groups of 5 weighed and marked white mice. In the inhibition tests, intraperitoneal injections of 0.5 cc of different doses of A-Methopterin were begun 24 hours later. In the therapeutic test, injections were begun after 3 to 7 days of tumor growth. In all instances, injections were given twice daily at 6-hour intervals for 7 consecutive days. If the animals showed definite signs of a toxic effect of the drug, administration was omitted until recovery had taken place. At the higher dosage (2.5-2.0 mg/kg/day) 3 or 4 omissions were often necessary. Below this level the drug was well tolerated.

Following the period of injections the animals were weighed and the size of their tumors determined by measurement in 2 diameters with calipers. The size of the tumors was then compared with those of the untreated controls and tumor growth was graded according to the following scheme: 1) Inconclusive, in groups of animals where 3 or more died, 2) No effect, when the largest diameter was ¾ or more of the diameter of the control tumors, 3) Moderate effect, when the diameter was ¼ to ¾ of the diameter of the control tumors, 4) Marked inhibition when the diameter was ¼ or less of that of the control tumors; actually, the volume of such a tumor would be 1/64 or less of the control if tumors may be considered spherical.

The animals were again weighed and their tumors measured at the end of the second week.

Results. Groups of 5 mice implanted with the Sarcoma 180 one day previously were injected intraperitoneally with daily doses of A-Methopterin at the following levels: 2.5 mg, 2.0 mg, 1.5 mg, and 1 mg/kg. Deaths due to the toxicity of the material were recorded during the 7-day period of injection. Tumor measurements were made at the end of the period and the effect of the substance on the tumor was evaluated. These data are summarized in Table I.

It is clear that A-Methopterin has a definite inhibitory effect on the growth of Sarcoma 180 at all the levels of drug above 1 mg/kg/day. The drug killed 46% and 18%, respectively, in the groups of mice receiving 2.5 and 2.0 mg/kg/day. At the lower dosages 7% and 5% of the mice receiving 1.5 and 1.0 mg died during the treatment. Male mice appeared to tolerate the drug better than female mice. The best results were obtained at the 1.5 mg dose where a definite effect was noted in almost all instances with little evidence of toxicity. The average weight loss of this group was 1.0 g as contrasted to a gain of 0.5 g for the controls. Fig. 1 shows the typical inhibition effect on the tumor of the injection of A-Methopterin at the level of 1.5 mg/kg/day.

The tumors have never been completely destroyed. When the injections are stopped, the small tumors grow normally.

When the tumors were allowed to grow for 3 to 7 days before the injections were begun, inhibition of growth was apparent in practically all instances. Of the 15 groups of mice receiving 2 mg/kg/day, inhibition was marked in 3 groups, moderate in 11 groups and absent in one group. Of the 24 groups receiving 1.5 mg/kg/day, inhibition was marked in 7, moderate in 16, and absent in one. The death rates for the 2 dosages were 12% and 16%, respectively. It is doubtful that these figures represent true toxicity deaths, because many of the tumors were so large at the time injections were initiated, that some of the mice probably died from the effects of tumor growth. The effect of A-Methopterin was definite although not as marked as in the groups of mice injected 24 hours after implantation.

In a few experiments a single injection of 50 mg/kg was administered when the tumor had grown one day. An inhibitory effect was evident when the tumors were measured a week later. In one group implanted 24 hours previously which received one injection of 50 mg/kg, small doses (0.5 mg/kg/day) were administered for 7 days. When the tumors were measured, they were very small but grew when the injections were stopped. The development of 7-day-old tumors was not affected by the injection of the single large dose.

Discussion. A-Methopterin has been shown to have a definite and consistent inhibitory effect on the growth of the transplantable mouse Sarcoma 180. In another report (Sugiura, Moore, Stock)[4] the folic acid antagonist, Aminopterin, was shown to have a similar effect; however, marked inhibition could be demonstrated only when the drug was administered in amounts which killed a large per cent of the mice. A-Methopterin appears to exhibit a more favorable therapeutic index. It has been outstanding in its effect among numerous compounds which might interfere with the utilization of folic acid or possibly with the synthesis of nucleic acid. In fact, it has been the most effective compound of over 700 miscellaneous compounds that have been screened. It is therefore advanced as a compound worthy of further experimental study and for clinical trial in various types of cancer.

Summary. The compound 4-Amino-N[10]-methyl pteroylglutamic acid, has shown the ability to inhibit the growth of the transplantable mouse Sarcoma 180 when administered intraperitoneally in concentrations of 1.5 mg/kg each day for 7 days. At this dosage very few mice died from drug toxicity. The inhibition is most apparent when the compound is administered early in the development of the tumor.

Beneficial Effects of Liver on Growth and Survival in the Immature Hyperthyroid Mouse.*

B. H. ERSHOFF.

Emory W. Thurston Laboratories, Los Angeles, and Department of Biochemistry and Nutrition, University of Southern California, Los Angeles.

Available data indicate that desiccated whole liver will prolong survival and counteract the growth retardation of immature rats fed massive doses of thyroactive materials.[1,2] The protective factor is distinct from any of the known nutrients and is retained in the water-insoluble fraction of liver.[3,4] The present experiment was undertaken to determine the effects of liver and liver fractions on growth and survival in the immature hyperthyroid mouse.

1949 (June 27) - Dr. Rhoads on the cover of Time Magazine as "Cancer-Fighter"

[HP005V][GDrive]
Text of full article : [HP005X][GDrive]
Mentioned : Cornelius Packard "Dusty" Rhoads (born 1898) / Dr. Alice E. Moore (born 1908) /

Even as hospitals go, Manhattan's famed Memorial Hospital is not a light-hearted place. Its corridors never echo with the happy sounds of a maternity ward. No one is there because of minor ailments or for a good rest. Most of the patients know that their chances of recovery, though somewhat better every year, are poor indeed. Visitors passing through the lobby often look stunned by grief. Memorial is a tragic place because its patients are victims of cancer.

Room 1O2L, a short walk down an immaculate corridor, is one of the most cheerful-seeming places in the hospital. Divided by stiff brown curtains into examination booths, it rings on Friday mornings with the voices of children. A little boy with a Tommy gun shoots sparks at a white-coated doctor, and a plump little girl cradles her doll. In a corner, a nurse in a starched white uniform peers through a microscope and makes a click-click sound with a small, sharp-voiced machine. She is counting in some child's blood the deadly white cells of leukemia: cancer of the blood. All the children in 1O2L of a Friday morning have leukemia, for which no cure is known. All of them, as medicine's knowledge stands at present, will die of the disease.

Tower of Hope. Last week, as he does every week, a man with short-cropped, iron-grey hair, blue eyes and an easy smile stopped in at Room 102L. Dr.

Cornelius Packard Rhoads, director of Memorial, the world's biggest cancer hospital, is an outstanding symbol of medicine's determined campaign against a disease which causes one out of every seven deaths in the U.S. Dr. Rhoads also heads the Sloan-Kettering Institute for Cancer Research, whose 14 stories rise beside the hospital. In this tower of hope, the world's most ambitious cancer research laboratory, highly specialized scientists and technicians experiment endlessly in the war against cancer; from it have come strange new treatments that have, so far, kept many leukemic children alive.

"We can help only 25%," says Dr. Rhoads, "and they have remissions only. Their disease will recur and recur, perhaps in more violent form. Some people ask, 'Why keep them alive, if they must die eventually?' But we're moving faster now. Perhaps, before they exhaust their last remission, we'll have something really good. And you've seen how happy they are."

The Wartime Method. Dr. Rhoads's jobs as head of Memorial and of Sloan-Kettering allow him little time for his favorite recreation—sailing. Like most men named Rhoads, he is called "Dusty" by his friends. Born in Springfield. Mass. 51 years ago, he graduated from-Harvard Medical School in 1924. He has long been a successful medical scientist, and today he could be mistaken for the go-getting president of a big university.

In World War II, Dr. Rhoads was chief of the Medical Division of the Army's Chemical Warfare Service. The gas program turned out to be "preventive" only; the enemy did not use gas. But the experience made a lasting impression on him. He came away from war work with enormous respect for what can be accomplished when scientists, who are notoriously in dividualistic, get together. Driven by wartime urgency, the scientists abandoned their jealousies and rivalries, submerged their temperaments and attacked each problem cooperatively from every possible angle. High-pressure wartime science achieved in a few years what would have taken decades of sauntering peacetime effort. Why not, thought Rhoads, use the wartime method on cancer?

What Dr. Rhoads thinks he is apt to say —loudly, clearly and often to a great many people. His persuasive tongue, a rare gift among scientists, had some effect. In 1945 Alfred P. Sloan Jr., chairman of the board of General Motors, gave $4,000,000 to set up the Sloan-Kettering Institute, with Rhoads at its head. Other sources of funds promised lavish support. The impressive building was finished 18 months ago, and Rhoads began assembling a staff. "All I can do," he says, "is pick good men, give them opportunities and help them keep pointed at the target."

Among cancer men, who carry on their research work individually and in teams across the country, brisk Dr. Rhoads is not universally popular. A few worry because they think his position gives him too much power over cancer research. Rhoads himself knows that he runs the risk of being called highhanded and arbitrary, the head of a vast research organization that stamps out individualities. But he hopes that Memorial Hospital, with its pathetic patients, will supply some of the qualities of a wartime emergency.

"Some authorities," says Rhoads,"think that we cannot solve the cancer problem until we have made a great, basic, unexpected discovery, perhaps in some apparently unrelated field. I disagree. I think we know enough to go ahead now and make a frontal attack with all our forces. Anyway, that's what we are doing. We'll follow every promising lead, and we know a lot of them. If the ivory tower men solve the problem ahead of us, we won't feel we've wasted our time."

Gangster Cells. The "cancer problem," as pathologists call it, is one of the strangest and subtlest that medicine has faced. Cancer is not an outside enemy that can be fought in the open like a foreign invader. It is civil war among the body's own cells, and it runs through all of nature like a red fiber of ruin spun into the thread of life. All vertebrates, including frogs and fish, get cancer. In all probability, the experts say, invertebrates and plants have cancer too.

As a normal thing, the several hundred trillion cells in a human body cooperate loyally, subordinating themselves to the body's higher life. Their functioning and their usually slow rate of multiplication are controlled, most scientists believe, by the chemical hormones which are poured into the blood by a set of regulating glands.

Sometimes, for reasons which medicine does not yet understand, a cell turns out to be different from normal cells. Most such "mutations," less competent than the normal cells, die and are absorbed by the body. But occasionally a variant cell appears that is disastrously competent.

Something in its chemistry allows it to defy the hormones that regulate the growth of ordinary cells. It multiplies wildly, growing into a useless mass of disorderly tissue. The tumor pushes among the normal cells, presses on nerves, thrusts organs aside or invades them. Often the gangster cells get into the blood and spread around the body like seeds carried by the wind. Where they lodge they grow into "metastases"—secondary tumors as lawless as the first one.

That is cancer: war between the body and its rebel cells. But it is not a two, sided civil war, because the body has almost no defenses. The body creates no antibodies against cancer as it does against diphtheria or typhoid. It builds no tissue walls to confine the destructive cells. It feeds them well, allows them to grow unchecked, and dies helplessly when they disrupt some vital function.

"The Nazis were rather like cancer," says Rhoads, growing philosophical as all scientists are apt to do when they think about cancer. "Starting with a variant cell, Hitler, the Nazis multiplied throughout the German nation, bringing it to destruction. It took external forces to kill the Nazi cancer."

Knife & Radiation. "External forces" are the business of Sloan-Kettering Institute and all the other centers of cancer research, which are spending something like $50 million in the U.S. annually. At present the only known cure for cancer is destruction: the surgeon's knife or radiation (X rays and radium). Such methods work well with some forms of cancer. Skin cancer, for instance, can nearly always be removed so completely that it does not recur. Other accessible cancers can be dealt with too, and surgical methods are improving constantly. A recent advance saves many patients who have a vital artery that has been attacked. An "artery bank" supplied from such sources as amputation cases makes it possible for the surgeon to replace a cancerous artery almost as if he were a plumber replacing a rusted pipe.

Not long ago, Memorial's doctors noticed that cancer patients, often reacted well after a serious operation, but died a few days later for no apparent reason. Sloan-Kettering's research men went to work to find an explanation, found that in such cases the patients had died because of a deficiency of potassium in the blood. When potassium was added in new cases, the patients picked up quickly and survived the operation. Dr. Rhoads believes that such improved surgery and treatment, combined with sufficiently early diagnosis, may save from cancer one-third to one-half of the people who now die of it. That would mean saving the lives of 6,000,000 to 9,000,000 Americans now living who are destined, on the basis of present statistics, to die of cancer.

Differential Effect. Surgery cannot help the other 9,000,000. Many cancers involve vital organs that cannot be disturbed, or metastases which spread so quickly and widely throughout the body that the surgeon cannot find and remove them all. To deal with such cancers some agent is needed that has a strong "differential effect," i.e., that kills cancer cells without hurting normal tissue. A few such drugs are already known, but they are only a start, and not good enough.

The trouble is that cancer cells are very like normal cells. An agent that hurts one generally hurts the other. Still, the gangster cells have differences. The very fact that they grow rapidly in a chemical medium, the blood, in which normal cells grow slowly, is sufficient proof that they are different. To find and

exploit the differences is the chief goal of Sloan-Kettering Institute. The problem is being attacked at all levels—from simple testing of promising drugs to long-range exploration of the internal workings of cells.

Every week dozens of new chemicals come to Sloan-Kettering from commercial laboratories, chemical houses, university scientists and medical men. Each is catalogued and given a number (to head off charges of favoritism). The more interesting ones, thought to have strong biological effects, are tried on experimental cancers planted in white mice.

Girls & Mice. This testing is a mass-production process which would be impossible on such a scale in a smaller laboratory. Girls in white uniforms sit at a table with cages of mice before them and bits of mouse cancer in glass trays.

Deftly a girl picks up a cancer fragment with a trocar (a tubular needle with a plunger inside). She grabs a faintly squeaking mouse, holds it by the scruff of its neck, efficiently jabs the trocar into the skin of its belly and up under a front leg. She plants the cancer by pushing it out with the plunger. Then she reaches for another mouse.-

When the cancer has had time to "take," the mouse is injected with a just-under-killing dose of the chemical to be tested. After a week or so, a girl kills the mouse by crushing its fragile skull. Then she slits open its belly skin and measures the cancer, which is usually by this time a grey-pink, rounded mass as big as a thumbnail. If the tumor has disappeared or has not grown as much as expected, the chemical is listed as promising enough for further testing.

Eggs & Tubes. Another type of testing is done on eggs. A girl technician examines a fertile egg under a strong light, finds the developing embryo, and cuts a square hole in the shell above it. She plants a bit of cancer on the embryo, and seals the hole with a glass window stuck on with wax. The egg is put in an incubator. As the embryo grows, the cancer grows too. The embryo's blood vessels turn aside to supply the cancer, which frequently grows until it is nearly as big as the chick. Drugs are tested by injecting them into the egg yolk, and noting through the window what they do to the cancer.

Another method is tissue culture. Bits of cancer tissue are stuck to the side of a test tube. A nutrient solution (made of such unlikely ingredients as extract of human placentas) is added. The tube is sealed and put on a vertical merry-go-round in an incubator. As the merry-go-round revolves slowly, the solution washes over the cancer tissue, which grows vigorously just as if it were in a living body. Drugs can be tested against it simply by adding them to the solution.

Sloan-Kettering now has 2,300 chemical agents on file, and has already tested some 1,500. Six of them proved to have a good "differential effect" against one or more types of mouse cancer. A couple of dozen had some lesser effect. According to Dr. C. Chester Stock, head of the Division of Experimental Chemotherapy, this record is by no means discouraging. As the records and experience accumulate, the scientists are learning how to predict whether a compound is worth testing. If a new one has a slight effect, one of its close relatives may prove better. And each slightly successful drug sets biochemists to figuring out why it worked at all.

Cell City. Long-range figuring-out is the duty of such men as Dr. George B. Brown, head of the Protein Chemistry Division. Dr. Brown and his assistants are studying the chemistry of both normal and cancer cells, looking for differences that they may exploit.

Cell chemistry is a maddeningly complicated study. It is known that cells contain certain chemicals, but they are not mixed together haphazardly like dissolved salts in a chemist's beaker. Each cell is like a great, complex metropolis. The individual citizens (atoms) are organized into intricate groups like the people of the city. Some groupings (e.g., the three-atom molecule of water) are as small and tight as families. Others are larger, like all the workers in one factory. The various groups interact constantly, their links forming and dissolving as the cell lives and grows. Certain single large molecules (analogous to the city government) are thought to affect all the cells.

To get the most rudimentary understanding of the workings of the living, changing cell is enormously difficult. It would be even harder without a new tool: nitrogen 15, a stable (nonradioactive) isotope of nitrogen. Chemically, nitrogen 15 is exactly like the common nitrogen 14. The cells cannot tell the difference. But since it is slightly heavier, nitrogen 15 can be measured accurately by a balky and expensive instrument called a mass spectrometer. If compounds containing nitrogen 15 instead of ordinary nitrogen are fed to cells, the scientists can tell with the mass spectrometer whether the cells have accepted them as food.

Such work is slow and expensive: nitrogen 15 costs $1,000 for a single study. But already Dr. Brown's group have had one outstanding, success in their study of a cell's reproductive system. They used an artificial compound called 2,6-diaminopu-rine, not yet isolated in nature, which they thought had a momentary existence inside the cell. The organic chemists synthesized some of this compound and turned it over to the chemotherapists. They thought that it might have the sought-for "differential effect" on lawless cancer cells.

Sure enough, "2,6" prolonged the life of leukemic mice by 60%. It destroyed or controlled rat tumors. It killed other tumors in test-tube cultures. On human patients, it acted as a palliative, but not a cure. It has secured "remissions," for instance, for a few leukemic children.

Promising Molds. Dr. Rhoads and his associates believe that no possibility, even faintly promising, should be neglected. One long shot is to look for something in the secretions of molds. One such secretion, penicillin, has a differential effect on bacteria: it kills bacteria but leaves human tissue unharmed. Molds might conceivably produce something with a differential effect on cancer cells.

In a cold, air-conditioned room in Sloan-Kettering, various molds (green or white mats) are growing in flasks. The program is still young, but already one mold has been found that secretes a substance with a slight differential effect on mouse tumors. Dr. Rhoads does not even want to talk about it yet. He has no "cancer penicillin."

Behind a door marked "No Visitors" (no one may enter who has not been properly immunized), works attractive [Dr. Alice E. Moore (born 1908)], a leading virus fancier. "I'm a virus girl," she says, "so I thought I'd try 'em." She tried influenza virus on cancerous mice. No effect. She tried the virus of herpes (inflammation of the skin and mucous membranes). No effect.

Then she turned to the deadly virus of Russian spring-and-summer encephalitis, injected it into the abdominal cavity of cancerous mice. In about two days the firm, round tumors turned into blobs of pus. All the cancer cells apparently died. But the virus then went on and attacked the nerves and brain. Four days later the mice, apparently cured of cancer, died of encephalitis. Nonetheless, the virus had shown a dramatic differential effect. It went first to the tumor and thrived there before attacking the brain.

Try the Viruses. There is a long list of things that Dr. Alice can do now to exploit her discovery—so many things that Dr. Rhoads is enlarging her dangerous laboratory. One is to try the encephalitis virus on monkeys. The laboratory strain has lived so long in mouse brains that it may have lost its ability to attack primates. If it proves harmless to monkeys, it probably will not hurt humans. The final step will be to try it on human cancer patients to see if it attacks their tumors.

Another thing that Dr. Alice hopes to do is to grow her virus for a long time in mouse tumors, transferring it from mouse to mouse as the tumors die. When grown on new food, viruses often change their ways. Dr. Alice hopes that the encephalitis virus might be taught to give up its taste for brain tissue while increasing its appetite for tumors.

If all these methods fail, there are plenty of other viruses to try against cancer. Some of them, comparatively harmless to normal human tissue, may attack tumors. If some such virus could be found or developed, it would be an ideal anti-cancer drug. Circulating through the body like a ferret through rat holes, it could hunt down every gangster cell.

Search the Soil. One of the most interesting programs at Sloan-Kettering is concerned not with the cancer cells, but the "soil" (as Dr. Rhoads calls it) in which they grow. Normal human cells often look startlingly like small, one-celled animals. But they are not free agents. Their growth is controlled and limited by the hormones in the blood. The most important hormones come from the gonads (testes and ovaries) and from the adrenals (small glands attached to the kidneys).

It has been known for a long time that the steroid hormones (socalled because they contain the "steroid" nucleus in common) are closely connected with cancer. The administration of sex hormones can both cause and prevent certain cancers in mice. Some cancer researchers hold to the theory that a complete understanding of the steroid hormones might tell why cancer occurs, how to cure it, perhaps even how to prevent it. The difficulty is that there are a great many steroid hormones. Their study requires such special methods and special apparatus that steroid work has become a recognized sub-subdivision of biochemistry. At Sloan-Kettering the experts in this mysterious field sit together at luncheon, speaking a special language.

Leading steroid man at Sloan-Kettering is short, round, German-born Dr. Konrad Dobriner. The raw material of his science is human urine, in which are found steroid "metabolites" (breakdown products from the hormones that the body has used and passed on). Dobriner's assistants collect urine for months or even years from the people they intend to study. They extract the steroids by a long series of tedious techniques, and identify them by their characteristic absorption of infrared light.

Glandular Orchestra. Dobriner has already achieved startling results. The urine of each person has a different steroid pattern, but in healthy, normal males & females there is a general similarity. In cancer patients, however, there is a striking difference. A new steroid, 11 hydroxy-etiocholanolone, almost always absent in healthy persons, shows up in about two out of three cancer patients.

A remarkable discovery came when a woman from whom Dobriner had been collecting urine for several years suddenly developed cancer of the breast. Dobriner found, on examining the stored extract from her urine, that she had been excreting the uncommon steroid for at least three years before her cancer developed. The tumor was removed surgically and the woman is now apparently in perfect health. But she still excretes the cancer-pointing steroid.

It looks to Dobriner as if the presence of the uncommon steroid may indicate not only cancer but sometimes an abnormal hormone situation that leads to development of cancer. "The endocrine system," he says, "consists of a number of glands that should be in harmony, like a symphony orchestra. We want to prove that in cancer the orchestra is haywire."

Dobriner points out that steroid identification is not a good test for early cancer. It is not sure; it takes too long, and it costs too much ($10,000 for a complete job). But he is cutting down the time and cost. As he collects more records, other startling facts are showing up. For instance, people with hypertension (high blood pressure) generally excrete a special steroid. No one knows why, but Dobriner hopes to find out. The mysterious steroids from the glandular orchestra are apparently concerned with all the changes in the body's cells. "If you want to know about cancer," says Dobriner, "you must also know about old age, hypertension and degeneration." Thus, cancer research may discover, as a sort of byproduct, what makes people grow old.

Human Laboratory. The most important of Sloan-Kettering's laboratories is the great hospital next door, including the Strang Prevention Clinic. Dr. Rulon W. Rawson, head of the Division of Clinical Investigation, explains that, after all, human patients are the best source of information about human cancer. Clinical investigation is a two-way street. Observation of patients, especially their reaction to treatment, gives clues for researchers to follow. When the laboratories develop some new method applicable to human beings, the hospital is the only conclusive place to try it out.

A good example of the interaction of research and clinical study is the work of Rawson's group and of Dr. L. D. Marinelli on the treatment of thyroid cancer with radioactive iodine. Since the thyroid gland eagerly absorbs iodine (which it uses to make a hormone), doctors have hoped that a cancerous thyroid would absorb radioactive iodine 131 in sufficient quantity to kill the unruly cells. Unfortunately, this effort was none too successful. The normal thyroid took up nearly all the iodine. The cancerous thyroid cells, particularly the metastases in distant parts of the body, took up so little that they were hardly damaged by the iodine's radioactivity.

Trained Metastases. Dr. Marinelli and his associates worked out a neat method of dealing with this difficulty. First they removed the patient's normal thyroid and with it the original cancer. This left the metastases which, they found, often consisted of cancer cells that retained faint remnants of the normal function of the thyroid. With the normal thyroid gone, the degenerate cells awoke and began to act like thyroids. Stimulated by the proper drugs, they began taking up iodine and making it into thyroid hormones. Then Dr. Marinelli gave radioactive iodine to the patient. The tumors, acting as pinchhitting thyroid glands, absorbed it readily, and were in some cases destroyed by the iodine's radiation.

Some types of thyroid cancer do not respond to this treatment. The cells cannot be trained to take up iodine and kill themselves. But many patients have been helped to some extent. In four of them the disease has been definitely checked, though not wiped out entirely.

More important, Dr. Rawson believes, is the proof this method gives that cancer cells are not "autonomous"; that in some cases, at least, they can be trained to resume some of the functions of the normal cells from which they are descended. If they can be trained, perhaps they can eventually be trained to destroy themselves.

Dread Decision. The patients in Memorial Hospital are never used as experimental animals. Neither are they denied any treatment, however new, that might possibly do them good. Virtually all patients beyond the help of surgery are willing to have new drugs and treatments tried on them.

In each individual case, the doctors have to make a grim decision. Should they prolong a life that is sure to be "unsatisfactory?" Should they, by prolonging life, place a crushing burden on the patient's family? Should they, in desperate cases when everything else has been tried, use a drug so dangerous that it may kill the patient immediately? Such questions have no single answer. The doctors decide each case separately, considering such matters as the painfulness of the treatment and the patient's chance for happiness during his possible remission.

Some cancer doctors admit that they have almost cracked up thinking about such things, and about their utter helplessness in hundreds of cases. Dr. Rhoads, too, has his moments of depression. He is sure that his method of concerted frontal attack, submerging niceties of scientific temperament, is correct. But he also knows that neither he nor his men nor anyone else in the world has yet found a cancer cure.

also knows that neither he nor his men nor anyone else in the world has yet found a cancer cure.

Perhaps ... Sloan-Kettering is certainly trying hard. From his office on the 13th floor, Dr. Rhoads can review the work of the world's most impressive array of cancer-fighting weapons: the eggs with their little glass windows, the tubes of cancer tissue on their merry-go-rounds, the rows of deft-fingered girls with the squeaking, doomed white mice, the dangerous viruses, the green and white molds, the thousands upon thousands of chemical agents, the scholarly chemists, physicists, biologists, clinicians all working in unison to defeat the common enemy: cancer.

Perhaps at that moment in Memorial Hospital, a life frayed with pain and dimmed with morphine is flickering down to the cold. Dr. Rhoads is no callous technician. His confident eyes grow sad when he hears of this everyday event. He looks out the window at the cluttered roofs of New York and at a great bridge roaring with traffic. "It needn't be," he says, "not always."

*Asked if she would be afraid of a mouse in her own home, one of the girls replied: "Oh yes. Those are fierce, wild mice."

*This colony of cancer cells, which grew from a single cell in 31 days, has begun to spill out of a tiny glass tube. The cells are magnified about 70 times.

Studies to determine whether these homologous cancer cells had a similar capacity for propagation in normal healthy human beings were undertaken at the Ohio State Penitentiary in collaboration with Charles Doan and Richard Brooks and with the cooperation of John Porterfield and R. W. Alvis, warden. From a large group of volunteers, 14 were chosen for the initial study. Methods were identical with the aforementioned ones, except that only tissue cultures were used, and all studies were done simultaneously in June 1956.

CITATION AND PRESENTATION OF THE ACADEMY MEDAL* TO F. PEYTON ROUS, M.D.

C. P. RHOADS
Director, the Sloan-Kettering Institute for Cancer Research, New York, N. Y.

As years pass it becomes more frequently in order for the somewhat younger individual to speak publicly, in tribute to a somewhat older one. To perform this function a pupil of the senior is usually selected, or at least one who has some direct scientific or other reason to be indebted to the recipient of the honor. To discharge his duties properly, moreover, the payer of tribute is expected to bring forward some unique twist of phrase which will distinguish or make memorable his comment.

Until recently I have never had the honor of working with Peyton Rous, and I have no gift of words adequate to discharge properly my responsibility on this occasion. My contact with this man has been, however, of such a peculiar, and to me inspiring, nature as to lead me to acquiesce with the suggestion that I refer to it publicly, in tribute to this notable recipient of the Academy Medal.

Since it is usual and useful to refer to biographical matters, I would remind you that Dr. Rous was graduated from Johns Hopkins University in 1900, and received his medical degree in 1905. He interned at the Hopkins Hospital in medicine, became interested in pathology and continued this interest at Michigan. He was called to the Rockefeller Institute in 1909 and has been there, and a leader there, since that time.

Recall, if you will, the role of Hopkins in the revolution in medical teaching and research under way then, the inspiration given to younger men by its very great faculty, and its unique point of view.

The problem of the control of cancer disease mounts steadily

* Presented at the Annual Meeting of The New York Academy of Medicine, January 8, 1959.

F. PEYTON ROUS, M.D.

AS YEARS pass it becomes more frequently in order for the somewhat younger individual to speak publicly, in tribute to a somewvhat older one. To perform this function a pupil of the senior is usually selected, or at least one who has some direct scientific or other reason to be

indebted to the recipient of the honor. To discharge his duties properly, moreover, the payer of tribute is expected to bring forward some unique twist of phrase which will distinguish or make memorable his comment.

Until recently I have never had the honor of working with Peyton Rous, and I have no gift of words adequate to discharge properly my responsibility on this occasion. My contact with this man has been, however, of such a peculiar, and to me inspiring, nature as to lead me

to acquiesce with the suggestion that I refer to it publicly, in tribute to this notable recipient of the Academy Medal.

Since it is usual and useful to refer to biographical matters, I would remind you that Dr. Rous was graduated from Johns Hopkins University in 1900, and received his medical degree in 1905. He interned at the Hopkins Hospital in medicine, became interested in pathology and continued this interest at Michigan. He was called to the Rockefeller Institute in 1909 and has been there, and a leader there, since that time.

Recall, if you will, the role of Hopkins in the revolution in medical teaching and research under way then, the inspiration given to younger men by its very great faculty, and its unique point of view.

The problem of the control of cancer disease mounts steadily in importance. The major steps toward its solution have been made by a relatively small number of individuals. Among these Peyton Rous was, in 1911, one of the first. Our modern knowledge of the neoplastic process has been constructed to a large extent around his contributions.

His original demonstration of the cell-free transmission of fowl neoplasms was complete, and at the same time revolutionary. It remained a storm center of discussion among workers in cancer research for forty years. Its significance for an understanding of cancer has been fully appreciated only recently. This work remains a landmark not only in the field of its direct application, but also in virology as a whole.

But Peyton Rous saw beyond the circumscribed area of a single technique. When its possibilities were temporarily exhausted by the limited knowledge of the time, he turned, with similar skill, to other fields.

Modern hematology, replete with knowledge and procedures, gives little hint of how mysterious were the mechanisms of blood generation and destruction thirty years ago. Transfusion was a major surgical undertaking. The preservation of blood was inconceivable, its destruction little understood, and its production a mystery. "Anemia" was a diagnosis almost as useless as "fever" had been before our knowledge of the bacterial etiology of disease. Peyton Rous and his associates went far to illuminate these biological recesses.

Immunology was also the gainer by his work. New knowledge of the source of antibodies was made available. The discovery of hydrocarbon carcinogens and of a virus-induced cancer of the mammal by [Dr. Richard Edwin Shope (born 1901)] brought additional new tools to hand. The complementary actions of the carcinogens and tumor viruses became a major step forward in cancer research. It contributed much to our thinking on hidden or latent viruses that may spring into action under some apparently unrelated stimulus.

I have recounted, perhaps inadequately, some part of the formal record. May I now refer to a more personal and largely unrecorded aspect of his work. This was his contact with and influence on younger men.

***As a young pathologist just entering the field of investigative medicine, I had early contact with Dr. Rous in his capacity as editor of the Journal of Experimental Medicine. I am afraid that I was a brash young man at the time, distinctly overestimating the importance of the manuscript I had submitted.** In retrospect, this was not surprising since the work had no value whatever.*

Dr. Rous, gravely and patiently, reviewed my efforts with me, demolished my conclusions, refuted my claims and made clear the proper use of my native tongue. He then rebuilt on the ruins such a clear picture of the problem, and the procedure required to solve it, that my conceit was converted almost imperceptibly to inspiration, my enthusiasm to resolution. As I left the generous, patient, and kindly man, I was no longer the same individual. I was, however, wholly convinced that if I worked very assiduously, with the greatest vigor, for a very long time, perhaps I could make a real contribution.

Nothing, please be assured, could have turned me then from a life in medical science.

And realize, if you will, that the world of medical research is now strongly influenced by many, many individuals, much more deserving than I, who chose that career because of Dr. Rous' unique capacity for making inspiration stick and become an irrevocable resolution.

May I then, express my deep feeling and that of many others by the following words in appreciation of Dr. Peyton Rous:

- *DETERMINATION WITHOUT DOGMATISM*
- *CONSISTENCY WITH CONSIDERATION*
- *WISDOM WITH GENEROSITY*
- *A MOST BELOVED PHYSICIAN*
- *TO WHOM SCIENCE OWES SO MUCH*
- *TO WHOM THE CHARACTER OF SCIENTISTS OWES MORE*

And may I then, Peyton, present to you the Medal of The New York Academy of Medicine, a small recognition of what you have meant to so many.

DR. RHOADS DIES; LED CANCER UNIT

Director of Sloan-Kettering Since '45 — Set Up Army Research Center in War

Dr. Cornelius Packard Rhoads, director of the Sloan-Kettering Institute for Cancer Research here since 1945, died of a heart attack at his summer home in Stonington, Conn., last night. He was 61 years old.

Dr. Rhoads also was scientific director of the Memorial Center for Cancer and Allied Diseases here.

As the scientific director of Sloan-Kettering, research unit of the Memorial Center (Memorial Hospital), Dr. Rhoades was head of one of the largest concentrated programs for the study, treatment and cure of cancer in the world.

Predicted Cure in Ten Years

"Dusty" Rhoads, as he was called by his friends, had long been hopeful that a chemical control of cancer would be found, and three years ago he predicted it would come within a decade.

He was born in Springfield, Mass., on June 20, 1898. His father, Dr. George H. Rhoads, was an ophthalmologist. His mother was the former Harriet Carney.

In 1920 Dr. Rhoads graduated from Bowdoin College. He then went to the Harvard Medical School, where he was named class president and graduated cum laude in 1924.

After serving a year's interneship in surgery at the Peter Bent Brigham Hospital in Boston, Dr. Rhoads was appointed a fellow of the Trudeau Sanitarium in northern New York State. He returned to Massachusetts in 1927 as an instructor in pathology at the Harvard Medical School and assistant pathologist at Boston City Hospital.

Dr. Cornelius P. Rhoads

Joined Rockefeller Institute

Coming to New York the next year, Dr. Rhoads joined the staff of the Rockefeller Institute for Medical Research. He held various posts as a pathologist and associate in research.

Dr. Rhoads was named director of Memorial Hospital in 1940, and of the Sloan-Kettering Institute five years later. With the latter appointment, he assumed the leadership of a staff of several hundred technicians, chemists, librarians, statisticians and laboratory assistants, as well as scientists who come to the organization from many parts of the wolrd. The project has been called "the world's largest and most scientific effort to destroy cancer."

During World War II, Dr. Rhoads, who served as a colonel in the Army Medical Corps, was chief of the medical division of the Chemical Warfare Service. In this capacity he directed the establishment of the toxicological research laboratory at Edgewood Arsenal, Md., and the medical research laboratory at Dugway Proving Ground in Utah. He also set up medical testing stations in Florida and the Panama Canal Zone.

Held Legion of Merit

In awarding the Legion of Merit to him, the Army cited Dr. Rhoads as having "developed new methods of diagnosis and treatment for the relief of injuries due to toxic chemicals, and perfected a compound to counter the effects of blister gas. He also developed equipment for detecting gas in air, food and water."

Another of his activities during that period was as chairman of the blood-procurement program and vice chairman of the committe on treatment of gas casualties of the National Research Council.

After the war Dr. Rhoads was special consultant on cancer to the United States Public Health Service and consultant to the Brookhaven (L. I.) National Laboratories of the Atomic Energy Commission. He also served in other posts connected with government programs.

Dr. Rhoads belonged to more than thirty professional medical and scientific bodies. A leading member of the American Cancer Society, he also held membership in the Society of Medical Jurisprudence and the American Society of Tropical Medicine.

His articles in medical journals numbered more than 100, and included fields of poliomyelitis, renal physiology, anemia, clinical biochemistry of gastric cancers, steroid metastasis in cancer and chemotherapy of cancer.

Urged 'Frontal Attack'

"Some authorities," Dr. Rhoades once said in an interview, "think that we cannot solve the cancer problem until we have made a great, basic, unexpected discovery, perhaps in some apparently unrelated field. I disagree. I think we know enough to go ahead and make a frontal attack with all our forces. * * * We'll follow every promising lead, and we know a lot of them. If the ivory-tower men solve the problems ahead of us, we won't feel we've wasted our time."

This interview, as others, was given by the quiet-spoken man with the close-cropped, iron-gray hair and blue eyes in room 102L at the hospital, as he surveyed his "tower of hope" and the fourteen-story Sloan-Kettering Institute hard by.

Dr. Rhoads leaves his wife, the former Katherine Southwick Colman.

A spokesman for Sloan-Kettering said funeral arrangements would be announced here today.

Prof Juergen Richt (Contact Francisco VEAS, Francisco.veas@ird.fr mobile:0681416506) : “Research and Infectious Diseases Mitigation Activities of the Center of Excellence for Emerging and Zoonotic Animal Diseases” - Department of Homeland Security in USA

Programs to control worldwide emerging zoonotic diseases are major challenges that one the most performing worldwide lab is doing with an outstanding network located around the World.

Professor Richt has created a huge scientific and technological platform generating solutions for emerging pathogens. This platform will be enlarged with the transfer to Kansas of the Plume Island lab in New York, which is the biggest lab in the World for dangerous emerging pathogens to create the National Bio and Agro-defense Facility (NBAF). The Laboratoire d'ImmunoPhysiopathologie Moléculaire Comparée

(IRD-UMR Ministère de la Défense) and its director Francisco Veas are proud to share with Montpellier's scientific, medical, veterinary and pharma community, an outstanding moment of basic and translational science.

Speaker Biography

Jurgen Richt, DVM, PhD is Regents Distinguished Professor of the Kansas State University, College of Veterinary Medicine Director, Department of Homeland Security Center of Excellence for Emerging and Zoonotic Animal Diseases

A deep fascination with the ability of an infectious agent to outsmart its host has been the driving force behind Jurgen Richt's expertise in diagnosing and treating zoonotic diseases -- those which can be transmitted from animals to humans or vice versa. Richt is a veterinary microbiologist who has worked with multiple agents of zoonotic potential, including bovine spongiform encephalopathy or mad cow disease, chronic wasting disease, animal influenza viruses, Rift Valley Fever virus, Borna virus and other emerging pathogens. Richt's career, which includes a seven-year assignment as lead scientist at the U.S. Department of Agriculture's National Animal Disease Center, has been spent developing novel testing methods and remedies for a number of animal and zoonotic diseases.

Richt joined Kansas State University in 2008 as Regents distinguished professor and Kansas Bioscience eminent scholar in the College of Veterinary Medicine's department of diagnostic medicine and pathobiology. Richt became the director of the Department of Homeland Security's Center of Excellence for Emerging and Zoonotic Animal Diseases, or CEEZAD, at Kansas State University in 2010.

As director, he leads an international network for scientific research involving 15 universities, various commercial firms and 25 principal investigators. In 2013 he was named a university distinguished professor, a lifelong title and the highest honor the university can bestow on its faculty.

Richt and colleagues were the first to generate prion protein-deficient cattle that are healthy and resistant to prion diseases. In his influenza research, Richt's laboratory was the first to establish a reverse genetics system for studying swine influenza virus pathogenesis in its natural host -- the pig. These studies led to the identification of influenza virulence factors and the development of a modified live virus vaccine based on a genetically engineered truncation within the NS1 gene. Richt and colleagues used the reconstructed 1918 influenza virus for experiments using the biosafety level-4 bio-containment facilities in Winnipeg, Canada.

At Kansas State University, Richt has established a research program that involves a multidisciplinary approach to solving both existing and emerging animal and zoonotic disease concerns. This includes the development of novel vaccines against threat diseases like Rift Valley Fever or avian flu as well as assays to rapidly detect these agents. Recently, Richt and colleagues developed a novel subunit vaccine for Rift Valley Fever.

Richt has authored or co-authored more than 170 peer-reviewed articles. His work has been published extensively, including in such prestigious journals as Nature Biotechnology, Science, Journal of Experimental Medicine, PNAS, Cell Host Microbe and Journal of Virology. He also holds a position on the prestigious scientific advisory board of the Scientific and Technical Review of the World Organization for Animal Health in Paris. In 2011, Richt received the Pfizer Animal Health Award for Research Excellence. Now, his aim has been to combine significant scientific research with the communication of results to both scientists and nonscientists.

Background[edit]

Roche was born in Brooklyn, New York.[1] He served for 23 years in the United States Navy before retiring with the rank of Captain in 1983. As a naval officer, his assignments included Principal Deputy Director of the State Department's Policy Planning Staff; Senior Professional Staff Member of the Senate Select Committee on Intelligence; and assistant director for the Defense Department's Office of Net Assessment. He commanded USS *Buchanan*, a guided missile destroyer, and was awarded the Arleigh Burke Fleet Trophy for the Navy's most improved combat unit in the Pacific in 1974.

Prior to this appointment, Secretary Roche held several executive positions with Northrop Grumman Corp., including corporate vice president and president, Electronic Sensors and Systems Sector. Prior to joining Northrop Grumman in 1984, he was Democratic Staff Director of the U.S. Senate Armed Services Committee.

Secretary of the Air Force[edit]

Secretary Roche served as a member of the Secretary of Defense's Policy Board and was a member of the Council of Foreign Relations and the International Institute of Strategic Studies. Roche was awarded various campaign ribbons and military medals.

Ethics investigation[edit]

Roche was also cited for ethics violations regarding the Air Force's decision to lease KC-767 tanker aircraft.[2]

In 2003, during the Air Force's deliberations concerning the replacement of KC-135 aircraft, Ms. Robin Cleveland, Associate Director of National Security Programs, OMB, emailed Dr. Roche asking his assistance in gaining employment with Northrup Grumman Corporation (for which he had once been a senior executive) after she left her position with the government. Dr. Roche did so and replied to Ms. Cleveland telling her so. This was a DoD ethics violation. The investigation found that Roche had 'misused his office for public gain' and used government communications to do so, but made no recommendations for action.[3]

Secretary of Defense Donald Rumsfeld saw no reason to pursue the matter.

Education[edit]

Roche at a Pentagon briefing.

- 1960 Bachelor of Science degree in language, literature and philosophy, Illinois Institute of Technology, Chicago

- 1966 Master of Science degree with distinction in operations research, U.S. Naval Postgraduate School, Monterey, California
- 1972 Doctorate degree in business administration, Harvard Graduate School of Business Administration, Cambridge, Massachusetts
- 2002 Honorary Doctorate, Illinois Institute of Technology
- 2003 Honorary Doctorate, St. Thomas Aquinas College, Sparkill, New York

Career chronology[edit]

- 1960–1983, commissioned United States Navy officer, retiring with the rank of captain
- 1983–1984, Democratic Staff Director, Senate Armed Services Committee, Washington, D.C.
- 1984–1989, vice president and director, Analysis Center, Northrop Grumman Corp., Washington, D.C.
- 1989–1991, vice president and special assistant to the chairman, president and chief executive officer, Northrop Grumman Corp., Los Angeles, California
- 1991–1992, vice president of Advanced Development and Planning, Northrop Grumman Corp., Los Angeles, California
- 1992–1996, Chief Advanced Development, Planning, and Public Affairs Officer, Northrop Grumman Corp., Los Angeles, California
- 1996–2001, corporate vice president and president, Electronic Sensors & Systems Sector, Northrop Grumman Corp., Baltimore, Maryland
- 2001–2005, Secretary of the Air Force, Washington, D.C.

Awards and honors[edit]

- Defense Superior Service Medal
- Legion of Merit
- Navy Commendation Medal
- Navy Expeditionary Medal
- National Defense Service Medal
- Vietnam Service Medal
- United States Navy Distinguished Public Service Medal
- 2003 Department of the Army Distinguished Civilian Service Award
- 2003 Illinois Institute of Technology Professional Achievement Award
- 2003 U.S. Air Force Order of the Sword

Nelson Aldrich Rockefeller (July 8, 1908 – January 26, 1979) was an American businessman and politician who served as the 41st vice president of the United States from December 1974 to January 1977, and previously as the 49th governor of New York from 1959 to 1973. He also served as assistant secretary of State for American Republic Affairs for Presidents Franklin D. Roosevelt and Harry S. Truman (1944–1945) as well as under secretary of Health, Education and Welfare under Dwight D. Eisenhower from 1953 to 1954. A grandson of billionaire John D. Rockefeller and a member of the wealthy Rockefeller family, he was a noted art collector and served as administrator of Rockefeller Center in Manhattan, New York City.

Rockefeller was a Republican who was often considered to be liberal, progressive,[1] or moderate. In an agreement that was termed the Treaty of Fifth Avenue, Rockefeller persuaded Richard Nixon to alter the Republican Party platform just before the 1960 Republican Convention. In his time, liberals in the Republican Party were called "Rockefeller Republicans". As Governor of New York from 1959 to 1973, Rockefeller's achievements included the expansion of the State University of New York, efforts to protect the environment, the construction of the Governor Nelson A. Rockefeller Empire State Plaza in Albany, increased facilities and personnel for medical care, and the creation of the New York State Council on the Arts.

After unsuccessfully seeking the Republican presidential nomination in 1960, 1964, and 1968, Rockefeller was appointed vice president of the United States under President Gerald Ford, who ascended to the presidency following the August 1974 resignation of Richard Nixon. Rockefeller was the second vice president appointed to the position under the 25th Amendment, following Ford himself. Rockefeller was not placed on the 1976 Republican ticket with Ford. He retired from politics in 1977 and died two years later.

As a businessman, Rockefeller was president and later chair of Rockefeller Center, Inc., and he formed the International Basic Economy Corporation in 1947. Rockefeller assembled a significant art collection and promoted public access to the arts. He served as trustee, treasurer, and president of the Museum of Modern Art, and founded the Museum of Primitive Art in 1954. In the area of philanthropy, he founded the Rockefeller Brothers Fund in 1940 with his four brothers and established the American International Association for Economic and Social Development in 1946.

Early life and education (1908–1930)

See also: Rockefeller family

Rockefeller was born on July 8, 1908 at 12:10 pm, in Bar Harbor, Maine.[2][3] Named Nelson Aldrich after his maternal grandfather Nelson W. Aldrich,[3] he was the second son and third child of financier and philanthropist John Davison Rockefeller Jr. and philanthropist and socialite Abigail "Abby" Aldrich.[2][3] He had two older siblings—Abby and John III—as well as three younger brothers: Laurance, Winthrop, and David.[4] Their father, John Jr., was the only son of Standard Oil co-founder John D. Rockefeller and schoolteacher Laura Spelman.[5] Their mother, Abby, was a daughter of Senator Nelson Wilmarth Aldrich and Abigail P. Greene.[6]

Rockefeller grew up in his family's homes in New York City (mainly at 10 West 54th Street), a country home in Pocantico Hills, New York, and a summer home in Seal Harbor, Maine.[4][7] The family also travelled widely.[8] He received his elementary, middle, and high school education at the Lincoln School in New York City, an experimental school administered by Teachers College of Columbia University and funded by the Rockefeller family.[4] Nelson was known to disappear on the way to school, and was once found exploring the cities sewer system. As a child, he was the "indisputable leader" of his brothers, becoming particularly close to Laurance.[9]

Although his parents saw potential for Nelson to be succeed in life, he was a poor student. Generally in the lower third of his class, he almost failed ninth grade and had undiagnosed Dyslexia. Nelson's biographer Joseph E. Persico wrote that as a child he "demonstrated a discipline that throughout life would serve him in lieu of brilliance." Although Nelson wasn't accepted into Princeton University, he got into Dartmouth College,[9] arriving on campus in 1926.[10] While in college, he met Mary Todhunter Clark at the summer home in Maine, and the two fell in love.[11] They were engaged in autumn 1929.[12] In 1930, he graduated cum laude with an A.B. degree in economics from Dartmouth College, where he was a member of Casque and Gauntlet (a senior society), Phi Beta Kappa, and Psi Upsilon.[13][14][15] Rockefeller and Mary were married after he graduated, on June 23, 1930, at Bala Cynwyd, Pennsylvania.[16]

Early career (1931–1939)

This section does not cite any sources. Please help improve this section by adding citations to reliable sources. Unsourced material may be challenged and removed.(April 2019) (Learn how and when to remove this template message)

Following his graduation, Rockefeller worked in a number of family-related businesses, including Chase National Bank; Rockefeller Center, Inc., joining the board of directors in 1931, serving as president, 1938–1945 and 1948–1951, and as chairman, 1945–1953 and 1956–1958; and Creole Petroleum Corporation, the Venezuelan subsidiary of Standard Oil of New Jersey, 1935–1940.

Rockefeller served as a member of the Westchester County Board of Health from 1933 to 1953. His service with Creole Petroleum led to his deep, lifelong interest in Latin America. He became fluent in the Spanish language.

Mid-career (1940–1958)

Coordinator of Inter-American Affairs (CIAA)

Nelson Rockefeller, Coordinator of Inter-American Affairs (1940)

In 1940, after he expressed his concern to President Franklin D. Roosevelt over Nazi influence in Latin America, the President appointed Rockfeller to the new position of Coordinator of Inter-American Affairs (CIAA) in the Office of the Coordinator of Inter-American Affairs (OCIAA).[17] Rockefeller was charged with overseeing a program of U.S. cooperation with the nations of Latin America to help raise the standard of living, to achieve better relations among the nations of the western hemisphere, and to counter rising Nazi influence in the region.[18] He facilitated this form of cultural diplomacy by collaborating with the Director of Latin American Relations at the CBS radio network Edmund A. Chester.[19]

Rockefeller (right) with Brazilian President Getúlio Vargas in 1942

The Roosevelt administration encouraged Hollywood to produce films to encourage positive relations with Latin America.[20] Rockefeller required changes in the movie Down Argentine Way (1940) because it was considered offensive to Argentines. It was much more popular in the United States than in Latin America. Charlie Chaplin's satirical The Great Dictator (1940) was banned in several countries.[21]

In the spring of 1943, Rockefeller supported extensive negotiations and mission of North American members of the Junior Chamber of Commerce to Latin America as Coordinator of Inter-American Affairs of the US State Department, establishing the Junior Chamber International after its first Inter-American Congress in December 1944 at Mexico City. After coming back from the Inter-American Congress, Rockefeller convinced his father, John D. Rockefeller Jr., to donate the land to the city of New York to build the foundations of what would later become the United Nations Headquarters.[22][23]

Assistant Secretary of State for American Republic Affairs

In 1944, President Roosevelt appointed Rockefeller Assistant Secretary of State for American Republic Affairs. As Assistant Secretary of State, he initiated the Inter-American Conference on Problems of War and Peace in 1945. The conference produced the Act of Chapultepec, which provided the framework for economic, social and defense cooperation among the nations of the Americas, and set the principle that an attack on one of these nations would be regarded as an attack on all and jointly resisted. Rockefeller signed the Act on behalf of the United States.[24]

Rockefeller was a member of the U.S. delegation at the United Nations Conference on International Organization at San Francisco in 1945; this gathering marked the UN's founding. At the Conference there was considerable opposition to the idea of permitting, within the UN charter, the formation of regional pacts such as the Act of Chapultepec. Rockefeller, who believed that the inclusion was essential, especially to U.S. policy in Latin America, successfully urged the need for regional pacts within the framework of the UN.[25] Rockefeller was also instrumental in persuading the UN to establish its headquarters in New York City.[22]

Nelson Rockefeller, Under Secretary of Health, Education and Welfare, makes a presentation on a proposed public/private health reinsurance program, 1954.

President Truman fired Rockefeller,[26] reversed his policies, and shut down the OCIAA.[27] Reich says that in official Washington, Rockefeller had become "a discredited figure, a pariah." He returned to New York.[28]

International Basic Economy Corporation (IBEC)

Rockefeller formed the International Basic Economy Corporation (IBEC) in 1947 to jointly continue the work he had begun as Coordinator of Inter-American Affairs. He intermittently served as president through 1958. IBEC was a for-profit business that established companies that would stimulate underdeveloped economies of certain countries. It was hoped that the success of these companies would encourage investors in those countries to set up competing or supporting businesses and further stimulate the local economy.[29] Rockefeller established model farms in Venezuela, Ecuador, and Brazil. He maintained a home at Monte Sacro, the farm in Venezuela.[30]

Chairman of the International Development Advisory Board

Rockefeller returned to public service in 1950 when President Harry S. Trumanappointed him Chairman of the International Development Advisory Board.[31] The Board was charged with developing a plan for implementing the President's Point IV program of providing foreign technical assistance. In 1952 President-Elect Dwight D. Eisenhower asked Rockefeller to Chair the President's Advisory Committee on Government Organization to recommend ways of improving efficiency and effectiveness of the executive branch of the federal government. Rockefeller recommended thirteen reorganization plans, all of which were implemented. The plans implemented organizational changes in the Department of Defense, the Office of Defense Mobilization and the Department of Agriculture. His recommendations also led to the creation of the Department of Health, Education and Welfare. Rockefeller was appointed Under-Secretary of this new department in 1953. Rockefeller was active in HEW's legislative program and implemented measures that added ten million people under the Social Security program.[32]

Special Assistant to the President for Foreign Affairs

In 1954, he was appointed Special Assistant to the President for Foreign Affairs (sometimes referred to as Special Assistant to the President for Psychological Warfare). He was tasked with providing the President with advice and assistance in developing programs by which the various departments of the government could counter Soviet foreign policy challenges. As part of this responsibility he was named as the President's representative on the Operations Coordinating Board, a committee of the National Security Council. The other members were the Undersecretary of State, the Deputy Secretary of Defense, the director of the Foreign Operations Administration, and the Central Intelligence Agency director. The OCB's purpose was to oversee coordinated execution of security policy and plans, including clandestine operations.[33]

Rockefeller broadly interpreted his directive and became an advocate for foreign economic aid as indispensable to national security. Most of Rockefeller's initiatives were blocked by Secretary of State John Foster Dulles and his Under Secretary, Herbert Hoover Jr., both traditionalists who resented what they perceived as outside interference from Rockefeller,[34] and by Treasury Secretary George M. Humphrey for financial reasons.[35] However, in June 1955 Rockefeller convened a week-long meeting of experts from various disciplines to assess the U.S. position in the psychological aspects of the Cold War and develop proposals that could give the U.S. the initiative at the upcoming Summit Conference in Geneva. The meeting was held at the Marine Corps school at Quantico, Virginia, and became known as the Quantico Study. The Quantico panel developed a proposal called "open skies" wherein the U.S. and the Soviet Union would exchange blueprints of military installations and agree to mutual aerial reconnaissance. Thus military buildups would be revealed and the danger of surprise attacks minimized. It was a counter proposal to the Soviet proposal of universal disarmament. The feeling was that the Soviets could not refuse the proposal if they were serious about disarmament.[36]

In March 1955, Rockefeller proposed the creation of the Planning Coordination Group, a small high level group that would plan and develop national security operations, both overt and covert.[37] The group consisted of the Undersecretary of State, the Deputy Secretary of Defense, the director the CIA, and Special Assistant Rockefeller as chairman. The group's purpose was to oversee CIA operation and other anti-communist actions. However, State Department officials and CIA Director Allen Dulles refused to cooperate with the group and its initiatives were stymied or ignored.[38] In September Rockefeller recommended the abolishment of the PCG, and in December he resigned as Special Assistant to the President.

Vice President Rockefeller (right) with Secretary of State Henry Kissinger, January 3, 1975.

In 1956, he created the Special Studies Project, a major seven-panel planning group directed by Henry Kissinger and funded by the Rockefeller Brothers Fund, of which he was then president. It was an ambitious study created to define the central problems and opportunities facing the U.S. in the future, and to clarify national purposes and objectives. The reports were published individually as they were released and were republished together in 1961 as Prospect for America: The Rockefeller Panel Reports.[39]

The Special Studies Project came into national prominence with the early release of its military subpanel's report, whose principal recommendation was a massive military buildup to counter a then-perceived military superiority threat posed by the USSR. The report was released two months after the October 1957 launch of Sputnik, and its recommendations were fully endorsed by Eisenhower in his January 1958 State of the Union address.[40]

This initial contact with Kissinger was to develop into a lifelong relationship; Kissinger was later to be described as his closest intellectual associate. From this period Rockefeller employed Kissinger as a personally funded part-time consultant, principally on foreign policy issues, until the appointment to his staff became full-time in late 1968. In 1969, when Kissinger entered Richard Nixon's administration, Rockefeller paid him $50,000 as a severance payment.[41]

Governor of New York (1959–1973)

Gov. Rockefeller meets with President Lyndon B. Johnson in 1968

Rockefeller resigned from the federal government in 1956 to focus on New York State and on national politics.[42] From September 1956 to April 1958, he chaired the Temporary State Commission on the Constitutional Convention.[43] That was followed by his chairmanship of the Special Legislative Committee on the Revision and Simplification of the Constitution.[43] In the state election of 1958, he was elected governor of New York by over 570,000 votes, defeating incumbent W. Averell Harriman, even though 1958 was a banner year for Democrats elsewhere in the nation.[44] Rockefeller was re-elected in the three subsequent elections in 1962, 1966 and 1970, increasing the state's role in education, environmental protection, transportation, housing, welfare, medical aid, civil rights, and the arts. To pay for the increased government spending, Rockefeller increased taxation - for example, a sales tax was introduced in New York in 1965.[45] He resigned three years into his fourth term and began to work at the Commission on Critical Choices for Americans.[46]

Abortion

Rockefeller supported reform of New York's abortion laws beginning around 1968. The proposals supported by his administration would not have repealed the long-standing prohibition, but would have expanded the exceptions allowed for the protection of the mother's health, or in circumstances of fetal abnormality. The reform bills did not pass. However, when an outright repeal of the prohibition managed to pass in 1970, Rockefeller signed it. In 1972, he vetoed another bill that would have restored the abortion ban. He said in his 1972 veto message, "I do not believe it right for one group to impose its vision of morality on an entire society."[47]

Arts and culture

Rockefeller created the first State Council on the Arts in the country, which became a model for the National Endowment for the Arts. He also oversaw the construction of the Saratoga Performing Arts Center in Saratoga Spa State Park.[48] He supported the bill, enacted in June 1966, which acquired Olana, home

of Hudson River School artist Frederic Edwin Church, as a state historic site.[49]

Buildings and public works

Rockefeller engaged in massive building projects that left a profound mark on the state of New York. (Some of his detractors claimed that he had an "Edifice Complex.")[50] He was personally interested in the planning, design, and construction of the many projects initiated during his administration, consistent with his interest in architecture. In addition, Rockefeller's construction programs included the US$2 billion South Mall in Albany, later renamed the Nelson A. Rockefeller Empire State Plaza by Gov. Hugh Carey in 1978. It is a 98-acre (40 ha) campus of skyscrapers housing state offices and public plazas punctuated by an egg-shaped arts center. Along with the Empire State Plaza, in 1966 Rockefeller proposed the construction of the Adam Clayton Powell Jr. State Office Building in Harlem. The building was ultimately completed in 1973. While in office he supported the construction of the World Trade Center.[51]

Civil rights

Rockefeller achieved virtual total prohibition of discrimination in housing and places of public accommodation. He outlawed job discrimination based on sex or age; increased by nearly 50% the number of African Americans and Hispanics holding state jobs; appointed women to head the largest number of state agencies in state history; prohibited discrimination against women in education, employment, housing and credit applications; admitted the first women to the State Police; initiated affirmative action programs for women in state government; and backed New York's ratification of the Equal Rights Amendment to the U.S. Constitution. He outlawed "block-busting" as a means of artificially depressing housing values and banned discrimination in the sale of all forms of insurance.[52]

Commission on Critical Choices for Americans

Rockefeller addresses a February 1975 meeting of the Commission on Critical Choices for Americans

In 1973, Rockefeller worked with former Delaware Governor Russell W. Peterson to establish the Commission on Critical Choices for Americans.[53] The Commission was a private study project on national and international policy similar to the Special Studies Project he led 15 years earlier.[54] It was made up of a nationally representative, bipartisan group of 42 prominent Americans drawn from far-ranging fields of interest who served on a voluntary basis. Members included the majority and minority leaders of both houses of Congress. The Commission gathered information and insights to better understand the problems facing America, and to present to the American public the "critical choices" to be made in facing those problems.[citation needed]

Rockefeller resigned as New York's governor in December 1973 in order to devote himself full-time to the commission's work as its chairman.[54] He continued in that position after being sworn in as vice president, serving until February 28, 1975.[55]

Conservation

Consistent with his personal interest in design and planning, Rockefeller began expansion of the New York State Parkssystem and improvement of park facilities. He persuaded voters to approve three major bond acts to raise more than $300 million for acquisition of park and forest preserve land[56] and he built or started 55 new state parks.[57] Rockefeller initiated studies of environmental issues, such as loss of agricultural land through development—an issue now characterized as "sprawl." In September 1968, Rockefeller appointed the Temporary Study Commission on the Future of the Adirondacks. This led to his introduction to the Legislature in 1971 of a bill to create the controversial Adirondack Park Agency,[58] which was designed to protect the Adirondack State Park from encroaching development. Also, he launched the Pure Waters Program, the first state bond issue to end water pollution; created the Department of Environmental Conservation; banned DDT and other pesticides; and established the Office of Parks and Recreation.[59]

Crime

During his 15 years as governor, Rockefeller doubled the size of the state police, established the New York State Police Academy, adopted the "stop and frisk" and "no-knock" laws to strengthen police powers, and authorized 228 additional state judgeships to reduce court congestion.[60] New York was the last state to have a mandatory death penalty for premeditated first degree murder. In 1963 Rockefeller signed legislation abandoning that and establishing a two-stage trial for murder cases with punishment determined in the second stage.[61] Rockefeller was a supporter of capital punishment and oversaw 14 executions by electrocution as governor.[62] The last execution, of Eddie Mays in 1963, remains to date the last execution in New York and was the last execution before Furman v. Georgia in the Northeast.[63] However, despite his personal support for capital punishment, Rockefeller signed a bill in 1965 to abolish the death penalty except in cases involving the murder of police officers.[64]

Rockefeller was also a supporter of the "law and order" platform.[65]

Attica prison riot

Main article: Attica Prison riot

On September 9, 1971, prisoners at the state penitentiary at Attica, NY, took control of a cell block and seized thirty-nine correctional officers as hostages. After four days of negotiations, Department of Correctional Services Commissioner Russell Oswald agreed to most of the inmates' demands for various reforms but refused to grant complete amnesty to the rioters, with passage out of the country and removal of the prison's superintendent. When negotiations stalled and the hostages appeared to be in imminent danger, Rockefeller ordered New York State Police and national guard troops to restore order and take back the prison on September 13. Thirty nine people died in the assault, including ten of the hostages, nine of which were killed by the State Police and National Guard soldiers. An additional eighty people were wounded in what was called "a turkey shoot" by state prosecutor Malcolm Bell.[66]

A later investigation showed all but three of the deaths were caused by the gunfire of the National Guard and police. The other three were inmates killed by other inmates at the beginning of the riot. Opponents blamed Rockefeller for these deaths in part because of his refusal to go to the prison and negotiate with the inmates, while his supporters, including many conservatives who had often vocally differed with him in the past, defended his actions as being necessary to the preservation of law and order. "I was trying to do the best I could to save the hostages, save the prisoners, restore order, and preserve our system without undertaking actions which could set a precedent which would go across this country like wildfire," Rockefeller later said.[67]

In a telephone call with President Nixon, Rockefeller explained the deaths by saying "that's life."[68]

Drugs

What became known as the "Rockefeller drug laws" were a product of Rockefeller's attempt to deal with the rapid increase in narcotics addiction and related crime. In 1962, he proposed a program of voluntary rehabilitation for addicted convicts rather than prison time. This was approved by the

legislature, but by 1966 it was evident that this program was not working, as most addicts chose short prison terms rather than three years of treatment. Rockefeller then turned to a program of compulsory treatment, rehabilitation, and aftercare for three years. While this program saw success in rehabilitating addicts, it did little to reduce the narcotics trade and associated crime. Rockefeller was also frustrated by his belief that the federal government was not doing anything significant to address the problem. Feeling that existing laws and the way they were being implemented did not solve the problem of the "drug pusher", and pressured by voters angry about the drug problem, Rockefeller proposed a hard-line approach. As approved by the legislature in 1973, the new drug laws included mandatory life sentences without the possibility of plea-bargaining or parole for all drug users, dealers, and those convicted of drug-related violent crimes; a $1,000 reward for information leading to the conviction of drug pushers; and removing less harsh penalties for youthful offenders. Public support for the measures was mixed, as were the results. They did not lead more addicts to seek rehabilitation as hoped, and ultimately did not solve the problem of drug trafficking. These were among the toughest drug laws in the United States when they were enacted and are still on the books, albeit in moderated form.[69] To carry out the rehabilitation program, Rockefeller created the State Narcotics Addiction Control Commission (later the State Drug Abuse Control Commission.) New York also provided the financial support for research in methadone maintenance and the administration of the largest methadone maintenance program in the US.[60]

Education

Rockefeller was the driving force in turning the State University of New York into the largest system of public higher education in the United States. Under his governorship it grew from 29 campuses and 38,000 full-time students to 72 campuses and 232,000 full-time students. Rockefeller championed the acquisition of the private University of Buffalo into the SUNY system, making the State University of New York at Buffalo, now the largest public university in New York.[70][71] In 1971, he championed the creation of Empire State College to provide higher education to adults by removing impediments to access such as time, location, and institutional processes.

Other accomplishments included more than quadrupling state aid to primary and secondary schools; providing the first state financial support for educational television; and requiring special education for children with disabilities in public schools.[72]

Housing

To create more low-income housing, Rockefeller created the New York State Urban Development Corporation (UDC), with unprecedented powers to override local zoning, condemn property, and create financing schemes to carry out desired development. The financing involved the creation of a new sort of bond—what came to be called "moral obligation" bonds. They were not backed by the full faith and credit of the State, but the quasi-public arrangements were meant to, and did, convey the impression that the State would not let them fail. Rockefeller is criticized in some quarters for having contributed to the "Too Big To Fail" phenomenon in U.S. finance in general.[73] (UDC is now called the Empire State Development Corporation.) By 1973, the Rockefeller administration had completed or started over 88,000 units of housing for limited income families and the aging.[74]

Miscellaneous programs

Rockefeller with labor leader David Dubinsky, Mayor Robert F. Wagner Jr., and Cardinal Spellman at the 1959 Labor Day Parade in New York City

Rockefeller worked with the legislature and unions to create generous pension programs for many public workers, such as teachers, professors, firefighters, police officers, and prison guards. He proposed the first statewide minimum wage law in the U.S. which was increased five times during his administration. Additional accomplishments of Rockefeller's fifteen years as governor of New York include initiating the state lottery and off-track betting; adopting modern treatment techniques in state mental hospitals to reduce the number of mentally ill patients by over 50%; creating the State Office of the Aging and constructing nearly 12,000 units of housing for the aging; the first mandatory seatbelt law in the US; and creating the State Consumer Protection Board.[75]

National Commission on Water Quality

In May 1973, President Richard Nixon appointed Rockefeller chairman of the National Commission on Water Quality. The Commission was charged with determining the technological, economic, social and environmental implications of meeting water quality standards mandated by the Federal Water Pollution Control Act Amendments of 1972. The Commission issued its report in March 1976 and he testified before Congress on its findings. Rockefeller served on the Commission until July 1, 1976.[citation needed]

Presidential Mission to Latin America

On February 17, 1969, President Nixon commissioned a study to assess the state of Latin America. Nixon appointed Rockefeller to direct the study. The poor relationship between the two politicians suggested that Nixon would not be that interested in the results of the study. There was a lack of interest for the region in the late 1960s to early 1970s.[76]

In April and May 1969, at the request of President Nixon, Rockefeller and a team of 23 advisors visited 20 American republics during four trips to solicit opinions of U.S. inter-American policies and to determine the needs and conditions of each country. Most of the trips turned out to be an embarrassment. Among the recommendations in Rockefeller's report to the President were preferential trade agreements with Latin American countries, refinancing the region's foreign debt, and removing bureaucratic impediments that prevented the efficient use of U.S. aid. The Nixon administration did little to implement the report's recommendations.[77] In his report preface, Rockefeller wrote the following:

There is general frustration over the failure to achieve a more rapid improvement in standards of living. The United States, because of its identification with the failure of the Alliance for Progress to live up to expectations, is blamed. People in the countries concerned also used our visit as an opportunity to demonstrate their frustrations with the failure of their own governments to meet their needs ... demonstrations that began over grievances were taken over and exacerbated by anti-US and subversive elements which sought to weaken the United States, and their own governments in the process.[76]

The major part of the Rockefeller report suggested a reduction of U.S. involvement, "we, in the United States, cannot determine the internal political structure of any other nation". Because there was little the United States should or could do toward changing the political atmosphere in other countries, there was no reason to attempt to use economic aid as a political tool. This was the justification to reduce economic aid in Latin America. The Rockefeller report called for some aid to continue, but the report recommended creating more effective aid programs.[76]

Transportation

In 1967 Rockefeller won approval of the largest state bond issue at the time ($2.5 billion) for the coordinated development of mass transportation, highways and airports. He initiated the creation or expansion of over 22,000 miles (35,000 km) of highway[78] including the Long Island Expressway, the Southern Tier Expressway, the Adirondack Northway, and Interstate 81 which vastly improved road transportation in the state of New York. Rockefeller introduced the state's first support for mass transportation. He reformed the governance of New York City's transportation system, creating the New York Metropolitan Transportation Authority (MTA) in 1965. The MTA merged the New York City subway system with the publicly owned Triborough Bridge and Tunnel Authority, the Long Island Rail Road, Staten Island Rapid Transit, and operation of lines that would later become Metro-North Railroad, along with the newly created MTA Bus Company, which were purchased by the state from private owners in a massive public bailout of bankrupt railroads and struggling private bus companies located in Queens, NY. He also created the State Department of Transportation.

In taking over control of the Triborough Bridge and Tunnel Authority, Rockefeller shifted power away from Robert Moses, and in doing so became the first politician to win such a battle with the master builder Moses in decades. Under the New York MTA, toll revenue collected from the bridges and tunnels, which had previously been used to build more bridges, tunnels, and highways, now went to support mass transportation operations, thus shifting costs from general state funds to the motorist. In one controversial move, Rockefeller abandoned one of Moses's most desired projects, a Long Island Soundbridge from Rye to Oyster Bay, in 1973 due to environmental opposition.

Welfare and Medicaid

In the area of public assistance the Rockefeller administration carried out the largest state medical care program for the needy in the United States under Medicaid; achieved the first major decline in New York State's welfare rolls since World War II; required employable welfare recipients to take available jobs or job training; began the state breakfast program for children in low income areas; and established the first state loan fund for nonprofit groups to start day-care centers.[78]

Presidential campaigns

This section needs additional citations for verification. Please help improve this article by adding citations to reliable sources. Unsourced material may be challenged and removed. (April 2019) (Learn how and when to remove this template message)

Rockefeller sought the Republican presidential nomination in 1960, 1964, and 1968.

1960

His bid in the 1960 primary ended early when then-Vice President Richard Nixon surged ahead in the polls. After quitting the campaign, Rockefeller backed Nixon and concentrated his efforts on introducing more moderate planks into Nixon's platform, partially succeeding in the Treaty of Fifth Avenue.

1964

Rockefeller, as the leader of the Republicans' "Eastern Establishment," began as the front-runner for the 1964 nominationagainst conservative Senator Barry Goldwater of Arizona, who led the conservative wing of the Republican Party.[79][80] In 1963, a year after Rockefeller's divorce from his first wife, he married Margaretta "Happy" Murphy, a divorcee with four children, which alienated many Republican married women. The divorce was widely condemned by politicians, such as liberal Senator Prescott Bush of Connecticut, who condemned his infidelity, divorce, and remarriage. Rockefeller finished third in the New Hampshire primary in March, behind write-in Henry Cabot Lodge II (from neighboring Massachusetts) and Goldwater. He then endured poor showings in several more of the party primaries before winning an upset in Oregon in May. Rockefeller took a strong lead in the California primary, and his team seemed so assured of his victory that it cut advertising funds in the last days of his campaign. However, the birth of Rockefeller's child three days before the California primary put the divorce and remarriage issue back in the minds of voters, and on primary election day, Rockefeller narrowly lost the California primary and dropped out of the race. At a discouraging point in the 1964 California primary campaign against Goldwater, his top political aide Stuart Spencer called on Rockefeller to "summon that fabled nexus of money, influence, and condescension known as the Eastern Establishment. 'You are looking at it, buddy,' Rockefeller told Spencer, 'I am all that is left.'".[81] Rockefeller exaggerated, but the collapse of his wing of the party was underway.[82]

However, at the Republican National Convention in San Francisco in July, Rockefeller was given five minutes to speak before the convention in defense of five amendments to the party platform put forth by the moderate wing of the Republican Party[83] to counter the Goldwater plank. He was booed and heckled for sixteen minutes while he stood firmly at the podium insisting on his right to speak.[84] However, Goldwater supporters claimed that the booing was from not the convention floor but the gallery. Rockefeller was reluctant to support Goldwater in the general election.[85] The conflict between Rockefeller and Goldwater would have lasting effects, as Goldwater would subsequently vote against Rockefeller's confirmation for the Vice Presidency in 1974 and became a key player in blocking Rockefeller from being on the 1976 presidential ticket.[citation needed]

Rockefeller's stump speeches often used the phrase "the brotherhood of man, under the fatherhood of God"; reporters covering his campaign came to abbreviate the expression as BOMFOG.[86]

Rockefeller campaigning for the Republican presidential nomination in 1968

1968

Rockefeller again sought the presidential nomination in the 1968 primaries. His opponents were Nixon and Governor Ronald Reagan of California. In the contest, Rockefeller again represented the liberals, Reagan representing the conservatives, and Nixon representing moderates and conservatives. Rather than formally announce his candidacy and enter the state primaries, Rockefeller spent the first half of 1968, alternating between hints that he would run and pronouncements that he would not be a candidate.[citation needed] Shortly before the Republican convention, Rockefeller finally let it be known that he was available to be the nominee, and he sought to round up uncommitted delegates and woo reluctant Nixon delegates to his banner, armed with public opinion polls that showed him doing better among voters than either Nixon or Reagan against Democrat Hubert Humphrey. Despite Rockefeller's efforts, Nixon won the nomination on the first ballot.[87]

President Gerald Ford, Susan Ford and Betty Ford.

Vice President (1974–1977)

See also: 1974 United States vice presidential confirmation

Upon President Nixon's resignation on August 9, 1974, Vice President Gerald Fordassumed the presidency. On August 20, Ford nominated Rockefeller to be the next Vice President of the United States. In considering potential nominees, Rockefeller was one of three primary candidates. The other two were then-United States Ambassador to NATO Donald Rumsfeld, whom Ford eventually chose as his Chief of Staff and later Secretary of Defense, and then-Republican National CommitteeChairman George H.W. Bush, who would eventually become Vice President in his own right for two terms and President for one term.[88]

While acknowledging that many conservatives opposed Rockefeller, Ford believed he would bring executive expertise to the administration and broaden the ticket's appeal if they ran in 1976, given Rockefeller's ability to attract support from constituencies that did not typically support Republicans, including organized labor, African Americans, Hispanics, and city dwellers. Ford also felt he could demonstrate his own self-confidence by selecting a strong personality like Rockefeller for the number two spot.[89] Although he had said he was "just not built for standby equipment",[90] Rockefeller accepted the President's request to serve as vice president:

It was entirely a question of there being a Constitutional crisis and a crisis of confidence on the part of the American people. ... . I felt there was a duty incumbent on any American who could do anything that would contribute to a restoration of confidence in the democratic process and in the integrity of government.

Rockefeller was also persuaded by Ford's promise to make him "a full partner" in his presidency, especially in domestic policy.[91]

Rockefeller underwent extended hearings before Congress, suffering embarrassment when it was revealed he made massive gifts to senior aides, such as Henry Kissinger, and used his personal fortune to finance a scurrilous biography of political opponent Arthur Goldberg.[92] He had also taken debatable deductions on his federal income taxes, and ultimately agreed to pay nearly one million dollars to settle the issue, but no illegalities were uncovered, and he was confirmed. Although conservative Republicans were not pleased that Rockefeller was picked, most of them voted for his confirmation anyway; nevertheless, a minority bloc (including Barry Goldwater, Jesse Helms and Trent Lott) voted against him.[93] Many conservative groups campaigned against Rockefeller's nomination, including the National Right to Life Committee, the American Conservative Union, and others. The New York Conservative Party also opposed his confirmation. On the left, Americans for Democratic Action opposed Rockefeller's confirmation because it said his wealth posed too much of a conflict of interest.[94]

The Senate had given its approval December 10, 1974, 90 to 7. The House confirmed his nomination 287 to 128 on December 19.[95] Beginning his service upon taking the oath of office on December 19, Rockefeller was the second person appointed vice president under the 25th Amendment—the first being Ford himself. Rockefeller often seemed concerned that Ford gave him little or no power, and few tasks, while he was vice president. Ford initially said he wanted Rockefeller to chair the Domestic Policy Council, but Ford's new White House staff had no intention of sharing power with the vice president and his staff.[96]

Vice President Rockefeller (right) and his wife Happy (second on left) entertain President Gerald R. Ford(left) his wife Betty (second on right) and their daughter Susan (center) at Number One Observatory Circle on September 7, 1975.

Rockefeller's attempt to take charge of domestic policy was thwarted by Chief of Staff Rumsfeld, who objected to policy makers reporting to the president through the vice president. When Rockefeller had one of his former aides, James Cannon, appointed executive director of the Domestic Council, Rumsfeld cut its budget. Rockefeller was excluded from the decision making process on many important issues. When he learned that Ford had proposed cuts in federal taxes and spending he responded: "This is the most important move the president has made, and I wasn't even consulted."[97] However, Ford appointed him to the Commission on the Organization of Government for the Conduct of Foreign Policy, and appointed him Chairman of the Commission on CIA Activities within the United States, the National Commission on Productivity, the Federal Compensation Committee, and the Committee on the Right to Privacy. Ford also put Rockefeller in charge of his "Whip Inflation Now" initiative.[citation needed]

While Rockefeller was Vice President, the official vice presidential residence was established at Number One Observatory Circle on the grounds of the United States Naval Observatory. This residence had previously been the residence of the Chief of Naval Operations. Previous vice presidents had been responsible for maintaining their own homes at their own expense, but the necessity of full-time Secret Service security had made this custom impractical. Rockefeller already had a well-secured Washington residence and never lived in the home as a principal residence, although he did host several official functions there. His wealth enabled him to donate millions of dollars of furnishings to the house.[citation needed]

Rockefeller was slow to make use of Air Force Two, the official vice-presidential aircraft. Instead, he continued to use his own Gulfstream (which had the callsign Executive Two as a private aircraft). Rockefeller felt he was saving taxpayer money this way. Finally the Secret Service convinced him it was costing more to fly agents around separately for his protective detail than it would for him to travel on Air Force Two with them.[98]

1976 election

With the moderate Ford facing continued difficulty in securing the support of conservative Republicans for the 1976 presidential nomination, and anticipating a challenge from the conservative Ronald Reagan, he considered the possibility of another running mate, and discussed it with Rockefeller. In November 1975, Rockefeller offered to withdraw. Ford eventually concurred, and in explaining his decision Rockefeller said that he "didn't come down (to Washington) to get caught up in party squabbles which only make it more difficult for the President in a very difficult time ..."[99][100]

After Ford was nominated at the 1976 Republican National Convention, Reagan, Barry Goldwater, and other prominent conservatives conditioned their support for Ford on his selection of a suitable vice presidential nominee. Ford considered several candidates, including moderate-to-liberal Republicans such as William Ruckelshaus, and moderate-to-conservative Republicans including Bob Dole, and eventually decided upon Dole as the most acceptable to conservatives.[citation needed]

As of 2020, Ford is the last incumbent president to not have his incumbent vice president as his running mate. Ford later said not choosing Rockefeller was one of his biggest mistakes,[101] and "one of the few cowardly things I did in my life."[102]

Rockefeller campaigned actively for the Republican ticket, and Ford lost narrowly to Jimmy Carter. In what would become an iconic photo of the 1976 campaign, Rockefeller famously responded to hecklers at a rally in Binghamton, New York, with a raised middle finger.[103] "At the time, Rockefeller's finger flashing was scandalous. Writing about the moment 20 years later, Michael Oricchio of the San Jose Mercury News said the action became known

euphemistically as 'the Rockefeller gesture.'"[103]

Political ideology

Main article: Rockefeller Republican

Reflecting his interdisciplinary approach to problem solving, Rockefeller took a pragmatic approach to governing. In their book Rockefeller of New York: Executive Power in the State House, Robert Connery and Gerald Benjamin state, "Rockefeller was not committed to any ideology. Rather, he considered himself a practical problem solver, much more interested in defining problems and finding solutions around which he could unite support sufficient to ensure their enactment in legislation than in following either a strictly liberal or strictly conservative course. Rockefeller's programs did not consistently follow either liberal or conservative ideology." Early fiscal policies were conservative while later ones were not so. In the later years of his administration "conservative decisions on social programs were paralleled by liberal ones on environmental issues."[104] Rockefeller was opposed by conservatives in the GOP such as Barry Goldwater and Ronald Reagan because of his liberal political views. As governor, Rockefeller spent more than his predecessors.[105] Rockefeller expanded the state's infrastructure, increased spending on education including a massive expansion of the State University of New York, and increased the state's involvement in environmental issues. Rockefeller had good relations with unions, especially the construction trades, which benefited from his extensive building programs.[citation needed]

In foreign affairs, Rockefeller supported U.S. involvement in the United Nations as well as U.S. foreign aid. He also supported the U.S.'s fight against communism and its membership in NATO. As a result of Rockefeller's policies, some conservatives sought to gain leverage by creating the Conservative Party of New York. The small party acted as a minor counterweight to the Liberal Party of New York.[106] The most common criticism of Rockefeller's governorship of New York is that he tried to do too much too fast, vastly increasing the level of state debt which later contributed to New York's fiscal crisis in 1975.[107] Rockefeller created some 230 public-benefit authorities like the Urban Development Corporation. They were often used to issue bonds in order to avoid the requirement of a vote of the people for the issuance of a bond; such authority-issued bonds bore higher interest than if they had been issued directly by the state. The state budget went from $2.04 billion in 1959–60 to $8.8 billion in his last year, 1973–74. "Rockefeller sought and obtained eight tax increases during his fifteen years in office."[108] "During his administration, the tax burden rose to a higher level than in any other state, and the incidence of taxation shifted, with a greater share being borne by the individual taxpayer."[109]

Philanthropy and art patronage

Rockefeller served as Chairman of Rockefeller Center, Inc., (1945–53 and 1956–58) and began a program of physical expansion there. He and his four brothers established the Rockefeller Brothers Fund, a philanthropy, in 1940; he served as a trustee from 1940–1975 and 1977–1979 and as president in 1956. He established the American International Association for Economic and Social Development (AIA) in 1946. AIA was a philanthropy for the dissemination of technical and managerial expertise and equipment to underdeveloped countries to support grass-roots efforts in overcoming illiteracy, disease and poverty.[110]

Rockefeller served as a trustee of the Museum of Modern Art from 1932 to 1979. He also served as treasurer, 1935–1939, and president, 1939–1941 and 1946–1953. In 1933 Rockefeller was a member of the committee selecting art for the new Rockefeller Center. For the wall opposite the main entrance of 30 Rockefeller Plaza Nelson Rockefeller wanted Henri Matisse or Pablo Picasso to paint a mural because he favored their modern style, but neither was available. Diego Riverawas one of Nelson Rockefeller's mother's favorite artists and therefore was commissioned to create the huge mural. He was given a theme: New Frontiers. Rockefeller wanted the painting to make people pause and think. Rivera submitted a sketch for a mural entitled Man at the Crossroads Looking with Hope and High Vision to the Choosing of a New and Better Future. The sketch featured an anonymous man at the center. However, when it was painted the work caused great controversy due to the inclusion of a painting of Lenin (depicting communism) just off-center.[111] The Directors of Rockefeller Center objected and Rockefeller asked Rivera to change the face of Lenin to that of an unknown laborer's face as was originally intended, but the painter refused.

The work was paid for on May 22, 1933, and immediately draped. Rockefeller suggested that the fresco could be donated to the Museum of Modern Art, but the trustees of the museum were not interested.[112] People protested but it remained covered until the early weeks of 1934, when it was smashed by workers and hauled away in wheelbarrows. Rivera responded by saying that it was "cultural vandalism". At Rockefeller Center in its place is a mural by Jose Maria Sert which includes an image of Abraham Lincoln. The Rockefeller-Rivera dispute is covered in the films Cradle Will Rock and Frida.

Rockefeller was a noted collector of both modern and non-Western art. During his governorship, New York State acquired major works of art for the new Empire State Plaza in Albany. He continued his mother's work at the Museum of Modern Artas president, and turned the basement of his Kykuit mansion into a gallery while placing works of sculpture around the grounds (an activity he enjoyed personally supervising, frequently moving the pieces from place to place by helicopter). While he was overseeing construction of the State University of New York system, Rockefeller built, in collaboration with his lifelong friend Roy Neuberger, the Philip Johnson-designed Neuberger Museum on the campus of the State University of New York at Purchase.

He commissioned Master Santiago Martínez Delgado to make a canvas mural for the Bank of New York (City Bank) in Bogotá, Colombia; this ended up being the last work of the artist, as he died while finishing it.

Rockefeller's early visits to Mexico kindled a collecting interest in pre-Columbian and contemporary Mexican art, to which he added works of traditional African and Pacific Island art. In 1954 he established the Museum of Primitive Art devoted to the indigenous art of the Americas, Africa, Oceania and early Asia and Europe. His personal collection formed the core of the collection. "In 1956, Frederic Huntington Douglas was named honorary Curator of the American Indian section of the Nelson Rockefeller Museum of Native Arts in New York."[113] The museum opened to the public in 1957 in a townhouse on West 54th Street in New York City. In 1969 he gave the museum's collection to the Metropolitan Museum of Art where it became the Michael C. Rockefeller Collection.

In 1978, Alfred A. Knopf published a book on primitive art from Rockefeller's collection. Rockefeller, impressed with the work of photographer Lee Boltin and editor/publisher Paul Anbinder on the book, co-founded Nelson Rockefeller Publications, Inc. with them, with the goal of publishing fine art books of high quality. After Rockefeller's death less than a year later, the company continued as Hudson Hills Press, Inc.

In 1977 he founded Nelson Rockefeller Collection, Inc., (NRC) an art reproduction company that produced and sold licensed reproductions of selected works from Rockefeller's collection. In the introduction to the NRC catalog he stated he was motivated by his desire to share with others "the joy of living with these beautiful objects."

Personal life

This section needs additional citations for verification. Please help improve this article by adding citations to reliable sources. Unsourced material may be challenged and removed. (April 2019) (Learn how and when to remove this template message)

On June 23, 1930, Rockefeller married Mary Todhunter Clark.[16] They had five children: Rodman Clark Rockefeller, Ann Rockefeller, Steven Clark Rockefeller, and twins Michael Clark Rockefeller and Mary Rockefeller. Michael Rockefeller disappeared in New Guinea in November 1961. He is presumed to have drowned while trying to swim to shore after his dugout canoe capsized.

Nelson and Mary Rockefeller were divorced in 1962. On May 4, 1963, Rockefeller married Margaretta Large "Happy" Fitler. They had two sons together: Nelson Aldrich Rockefeller Jr. and Mark Fitler Rockefeller.

With his first wife, Rockefeller had lived at the three top floors at 810 Fifth Avenue. After his divorce and second marriage, Mary Rockefeller kept the two top floors of the triplex apartment.[114] The apartment was expanded by purchasing a floor of 812 Fifth Avenue. The two spaces connected via a flight of six steps.[115] Nelson and Happy Rockefeller used the entrance at 812 Fifth, while his first wife entered through 810 Fifth.[116] They remained married until his death.

Rockefeller engaged in numerous extramarital affairs during his marriages. His first wife resented his adultery, which was one of the main reasons for their divorce.[117] Rockefeller convinced his first wife early in the marriage that they should live separate lives but stay married for the sake of public appearances and the children.[118]

There has been speculation surrounding Malinda Fitler Murphy (b.1960), the youngest daughter of Happy Rockefeller and Dr. James Slater Murphy, with many in the Rockefeller inner circle believing her to be Nelson Rockefeller's daughter. In his diary, Rockefeller intimate Ken Riland used a tone of knowing irony when mentioning Malinda, putting the word stepfather in quotes. Ellen, the wife of Wally Harrison, the architect and Rockefeller confidant, claimed that Malinda's parentage was an open secret among Rockefeller associates.[118]

Rockefeller was a patient of famous psychic Edgar Cayce.[119]

Death

Rockefeller and President Jimmy Carter in October 1977

Rockefeller died on January 26, 1979 from a heart attack.[120] He was 70.[121] An initial report incorrectly stated that he died at his desk in his office at Rockefeller Center.[122][123] However, the report was soon corrected to state that Rockefeller actually had the fatal heart attack at another location: a townhouse he owned at 13 West 54th Street.[124] The heart attack occurred in the late evening in the presence of Megan Marshack, a 25-year-old aide.[125] After Rockefeller suffered the heart attack, Marshack called her friend, news reporter Ponchitta Pierce, to the townhouse; Pierce phoned an ambulance approximately an hour after the heart attack.[126]

Rockefeller's remains were cremated at Ferncliff Cemetery in nearby Hartsdale, New York. On January 29, 1979, family and close friends gathered to inter his ashes in the private Rockefeller family cemetery in Sleepy Hollow, New York.[127] A memorial service was held at Riverside Church in Upper Manhattan on February 2; the service was attended by 2,200 people. Attendees included President Jimmy Carter and former Secretary of State Henry Kissinger.[128]

Speculation surrounding death

The circumstances of Rockefeller's death led to widespread speculation regarding a possible adulterous relationship between Rockefeller and Marshack.[129][130][131][132] Marshack had worked for Rockefeller when he served as vice president, had relocated to New York and continued to work for him after his term as vice president ended, and had received financial assistance from Rockefeller in purchasing and furnishing a condominium several doors down from his Manhattan townhouse.[130]

In a PBS documentary about the Rockefeller family, longtime Rockefeller aide Joseph E. Persico said: "It became known that [Rockefeller] had been alone with a young woman who worked for him, in undeniably intimate circumstances, and in the course of that evening had died from a heart attack."[133] Rockefeller's four oldest children issued a statement saying that they had conducted their own review, that they believed their father could not have been saved, and that all those who tried to help had acted responsibly. Neither Marshack nor the family has ever commented publicly on the circumstances surrounding Rockefeller's death.[134] The family would not consent to an autopsy.[135] In 2017, the New York Daily Newsstated that following Rockefeller's death, "it wasn't long before Johnny Carson could start drawing laughs merely by uttering the words 'Megan Marshack.'"[130]

Rocky Mountain Labs

Wikipedia Rocky Mountain Laboratories

Saved Wikipedia (Feb 20, 2021) : Rocky Mountain Laboratories

[HK0053][GDrive]

- Agency overview
- Formed 1928[1]
- Preceding agency Hygienic Laboratory
- Headquarters Hamilton, Montana
- Employees 400[1]
- Parent agency National Institute of Allergy and Infectious Disease, National Institutes of Health, United States Department of Health & Human Services

Rocky Mountain Laboratories (RML) is part of the NIH Intramural Research Program and is located in Hamilton, Montana. Operated by the National Institute of Allergy and Infectious Diseases, RML conducts research on maximum containment pathogens such as Ebola as well as research on prions and intracellular pathogens such as Coxiella burnetti and Francisella tularensis.[2][3][4] RML operates one of the few Biosafety level 4 laboratories in the United States, as well as Biosafety level 3 and ABSL3/4 laboratories.[5]

In February 2020, electron microscope images of SARS-CoV-2 were collected at RML.[6]

Early map of the Bitterroot valley. Area in red shows where spotted fever infection occurred

Although the construction of the first building of The Rocky Mountain Labs was completed in 1928, RML evolved as a result of research on Rocky Mountain spotted fever that began around 1900, in the Bitterroot Valley of Western Montana. Early settlers of the valley were plagued with a deadly disease of unknown origin that seemed to be concentrated on the west side of the Bitterroot River.

The “black measles” rash characteristic of later stages of spotted fever infection.

It was known locally as "black measles" because of its severe dark rash, and folk wisdom of the day suggested that infection occurred from drinking the melted snow water that gushed out of the west side canyons during spring runoff. Fatal in nearly 4 out of 5 adult cases, local residents appealed to the state governor for help.

Montana had been granted statehood in 1889, and in 1901, the Montana State Board of Health was created. Its first priority was to bring health scientists to the Bitterroot Valley to investigate the cause, treatment and prevention of spotted fever. During the next three decades a memorable cast of characters was engaged in a drama that provided an interesting chapter in the annals of medical history.

Howard Taylor Ricketts, 1871-1910. Ricketts identified the causative agent of Rocky Mountain spotted fever.

Among the first was Dr. Howard Ricketts, a young pathologist from the University of Chicago, who in 1906, showed that the disease was transmitted by the bite of the Rocky Mountain wood tick (*Dermacentor andersoni*). Returning each summer to continue his work, by 1909, he had isolated the bacterial organism that was responsible for spotted fever, and that organism was later named *Rickettsia rickettsii* in his honor.

A state budget shortage made it questionable whether Montana could continue to fund Ricketts' research during the summer of 1910. Because of the uncertainty, he accepted funding to work on a typhus outbreak in Mexico City. Shortly before his work there was concluded, Ricketts himself contracted typhus and died soon after.

In front of the cabin that had been dubbed “Camp Venustus.” Clarence Birdseye of the U.S. Biological Survey stands in the doorway.

Clarence Birdseye was another interesting character to play a role in spotted fever research in the Bitterroot Valley. As part of an effort to understand the life cycle of the wood tick, Birdseye, a college student working for the US Biological Survey, spent the spring and early summer of 1910 shooting and trapping wild game and rodents to collect ticks. Reportedly, he bagged 717 small animals and collected nearly 4,500 ticks. After his work in Montana, Birdseye went to Labrador where he developed the concept of frozen foods and later established the company that bears his name.

Early Tick Research

In the years that followed, a number of state and federally funded researchers continued their investigations of spotted fever. The Montana State Board of Entomology under the direction of Dr. Robert Cooley developed a tick eradication program. Dipping vats were placed at several locations throughout the valley and ranchers were encouraged (by threat of quarantine) to drive their herds to the nearest station so that the cattle could swim through a trough of arsenic solution. However, preparing an arsenic solution strong enough to be effective, but not so strong as to burn the hides and udders of cattle, was accomplished by trial and error. This situation bolstered the resentment among local ranchers who already harbored a healthy distrust of government-imposed programs. In addition, two young brothers who had been helping at a dipping station on their family ranch both contracted the infection and died.

In June 1913, matters came to a head when the vat located near Florence was destroyed by dynamite and one outside of Hamilton was damaged with sledgehammers.

Dr. Roscoe Spencer, primarily responsible for the Spencer-Parker tick tissue vaccine.

Despite local hostility, work on spotted fever continued on several fronts. Within a few years Drs. Roscoe Spencer and Ralph Parker produced the first effective vaccine against the disease by emulsifying infected tick tissue and inactivating the rickettsiae with phenol.

The early facilities in which spotted fever research was conducted were makeshift at best. Ricketts worked in tents set up in the yard of the Northern Pacific Hospital north of the valley in **Missoula**.

Dr. Ralph Parker served as Director of the Rocky Mountain Labs from 1930, until his death in 1949.

Others worked out of cabins and farmhouses, and Parker for a time conducted his studies in a woodshed. Finally, in 1921, Parker found an abandoned schoolhouse on the west side of the valley and arranged to have it rented by the U.S. Public Health Service. The "Schoolhouse Lab," as it was known, was the facility where Spencer and Parker ground up tick tissue to produce their vaccine.

This deserted farmhouse in the Bitterroot foothills was rented in the spring of 1910, and converted to a laboratory for tick research. In 1909, several people in the vicinity had died of spotted fever.

Progress had been made toward controlling spotted fever, but much more awaited. In 1926, the Board of Entomology asked the state legislature to provide enough money to build a modern entomological laboratory. In the spring of 1927, the legislature appropriated $60,000 for the new building and a site in the town of Hamilton was chosen.

The woodshed used by Dr. Ralph Parker to perform tick research during the summer of 1920.

By this time, local sentiment toward medical investigators had softened considerably, but pockets of fear and distrust remained. Each spring newspapers reported new cases of the illness. While the annual number of deaths from spotted fever had fallen significantly from the record high of 17 in 1901, every year more victims succumbed to the disease. In addition, during the previous 16 years, 5 laboratory workers had become infected and perished.

The Lab is Built

When news hit the valley that a new laboratory would be built in Hamilton, a group of citizens immediately formed a coalition in opposition and it became clear that the facility would not be built without a fight. Unlike previous workstations, this site lay east of the river that bisects the valley.

Laboratory facilities at Victor, Montana, used from 1911-1916.

Since infection only occurred on the west side, residents worried that ticks might escape the facility and pose a danger to the town. To stop construction, homeowners in the neighborhood of the proposed site filed a lawsuit. At trial, plaintiffs argued that the location was particularly dangerous since it was only a block away from the high school. And, homeowners feared that property values in the area would plummet. Ultimately, the judge decided that construction could go forward, but in an effort to alleviate town fears, a small moat was built around the perimeter of the facility to be filled with water. Ticks, it was supposed, could not swim the moat.

The "schoolhouse lab" where Spencer and Parker produced the first effective vaccine against spotted fever. Extensively renovated over the years, this building has served as a museum and is currently the Hamilton Playhouse on Ricketts Road.

The building was completed in early 1928. It provided space for the state-administered control programs and rented space to the Public Health Service for Dr. Parker and his colleagues to continue research and vaccine production. By 1930, the laboratory employed four professionals and 22 support staff. In that year Parker was appointed scientific director, a role he continued in for the next 19 years. In February of 1932, the federal government purchased the facility from the state of Montana for $68,757 and several of the Board of Entomology employees were transferred to the Public Health Service.

Building 1 of the current RML campus was completed in 1928. Citizens filed an unsuccessful lawsuit to stop construction.

In 1937, RML became part of the National Institute of Health. During World War II, the laboratory joined in the war effort by becoming a "national vaccine

factory," producing vaccines to protect soldiers against spotted fever, typhus, and yellow fever. After the war, work at the lab returned to its primary mission of basic scientific research of infectious diseases. In 1948, the National Institute of Health was reorganized, and RML became part of what is now called the National Institute of Allergy and Infectious Diseases (NIAID).

Today, scientists at RML investigate a wide variety of infectious diseases. Supported by state-of-the-art genomics and electron microscopy units, current research includes the study of chronic wasting disease, chlamydia, Q-fever, tularemia, Salmonella, Staphylococcus, Lyme disease, relapsing fever, and plague. An Integrated Research Facility with maximum-containment laboratories allows scientists to use advanced technology in their quest to protect people from the emerging infectious diseases.

Three interesting reads on the story of early spotted fever research and the origins of the Rocky Mountain Laboratories are: Fighting Spotted Fever In the Rockies by Ester Gaskins Price, Naegele Printing Company, 1947; Rocky Mountain Spotted Fever, History of a Twentieth-Century Disease by Victoria A. Harden, Johns Hopkins University Press, 1990; Rocky Mountain Spotted Fever in Western Montana, Anatomy of a Pestilence by Robert N. Philip, Stoneydale Press, 2000.

Rocky Mountain Laboratories, NIAID, is a component of the National Institutes of Health (NIH). NIAID conducts and supports research—at NIH, throughout the United States, and worldwide—to study the causes of infectious and immune-mediated diseases, and to develop better means of preventing, diagnosing and treating these illnesses. News releases, fact sheets, and other NIAID-related materials are available on the NIAID website.

NIH, the nation's medical research agency, includes 27 Institutes and Centers and is a component of the U.S. Department of Health and Human Services. NIH is the primary federal agency conducting and supporting basic, clinical, and translational medical research, and is investigating the causes, treatments, and cures for both common and rare diseases. Visit NIH(link is external) for more information about its programs.

Galveston, Texas 77555-0609, USA

GRANT L. CAMPBELL: This panel session is entitled Laboratory Testing for West Nile Virus. We have five excellent panelists with us today. My co-moderator, Dr. Leo Grady is from the New York State Department of Health. My name is Roy [Grant] Campbell from CDC in Fort Collins, Colorado.

LEO J. GRADY: Good morning. Sitting directly to my right is Dr. Cinnia Huang from the New York State Department of Health; to her right is Dr. Laura Kramer, also from the New York State Department of Health. Dr. Rob Lanciotti from the CDC, Fort Collins, is next, and then comes Dr. John Roehrig, also from the CDC. At the end is Dr. Bob Shope from the University of Texas Medical Branch in Galveston, Texas. Each of the panelists will make a few brief comments about their involvement in laboratory testing, and then we will open the floor for discussion. Dr. Huang begins this session.

Page 179 (1st page of article)
[HP0068][GDrive]

CINNIA HUANG: Our lab is involved in human testing. The new state experiments with RT-PCR for West Nile virus are similar to what has been done at Fort Collins. The only difference we find is that a two-step regular RT-PCR is as sensitive as Taq-Man. The two-step RT-PCR is the protein protocol used now for the encephalitis PCR panel. Our panel includes different viruses, and West Nile is one of them. Based on our data, there are cases other than West Nile virus, such as enterovirus and the herpes virus, and the enterovirus season overlaps with West Nile virus. For this reason, our lab will continue to perform tests using PCR batteries.

ROBERT LANCIOTTI: I want to run through the most commonly used diagnostic tests, both for serology and for virus detection. For human diagnostics, our gold standards are the IgM and IgG ELISAs, and we confirm those by plaque-reduction neutralization testing. The molecular amplification tests, such as RT-PCR and TaqMan have limited usefulness in human diagnostics, and I think it's important to emphasize that. There are some people with a misconception that those could be front-line tests for human diagnostics. We have data showing—and it's limited data from the 1999 epidemic—that a positive PCR certainly is diagnostic but a negative doesn't mean a whole lot. There are a lot of other reasons. We have serologically confirmed cases, where you can't detect viral RNA, and I think that has a lot to do with the duration and level of viremia. Many times we're looking for virus pretty far out beyond the febrile phase, so the molecular tests have been most useful in the fatal cases, less useful in CSF, and even less in serum. Again, the ELISA serological tests are really our gold standard for human diagnostic testing. Virus isolation also should be attempted, but in many cases, the virus samples that we're getting to test and isolate are, in the diagnostic lab, beyond the viremic stage in many cases. But I think they're still important tests and ought to be attempted. For the surveillance of mosquito pools and birds, this is an application where the molecular tests are very useful—the RT-PCR and TaqMan. NASBA is another amplification technology that works very well. Those are the most commonly used tests, not only in our lab, but also in other state health departments. There's also immunofluorescence and immunohistochemistry, and there was a poster here describing antigen capture ELISA for West Nile detection as well. I think Dr. Kramer is going to talk about the importance of having a confirmatory algorithm in the lab. I think for any one of these tests, whether serological or virological, there needs to be a way of confirming positives. The other issue that I'll just mention is the importance of standardization. You may be aware that the CDC has done a lot of training in the last few months. We've trained, at this point, representatives from almost every state health department in the country, and we are now initiating a huge proficiency panel program where we're sending out both molecular and serology samples to every state health department that chooses to participate. This will be a large undertaking, but we think it's very important for states that anticipate testing to participate in the standardization proficiency panel.

LAURA KRAMER: To follow up on Dr. Lanciotti's comment, I think proficiency testing is crucial, especially with all the new labs coming online now doing surveillance testing. I also think that there's got to be quality control to make sure that what is positive is really positive. Because PCR is such a powerful and sensitive tool, it's a double-edged sword, and it's very easy to pick up contaminating RNA, either by aerosol or on your glove when you open up a tube. It's just so sensitive. We know that it detects less than one plaque-forming unit. We diluted avian tissues out 10^{-6},

LAURA KRAMER: To follow up on Dr. Lanciotti's comment, I think proficiency testing is crucial, especially with all the new labs coming online now doing surveillance testing. I also think that there's got to be quality control to make sure that what is positive is really positive. Because PCR is such a powerful and sensitive tool, it's a double-edged sword, and it's very easy to pick up contaminating RNA, either by aerosol or on your glove when you open up a tube. It's just so sensitive. We know that it detects less than one plaque-forming unit. We diluted avian tissues out 10−6, and we still detect a positive. So, it's very easy to think that you have a positive tissue and not really have it because your RNA is contaminated. I think some water blanks need to be included in all the assays, particularly with the bird tissues, where there's such a high load of viral RNA. The water blank needs to be in there from the very beginning. Where you're homogenizing the tissue, an aerosol is being created; it's closed, the system is closed, but when that tube gets opened it's very easy to carry

over some viral material and think that you have a host of new positives. So if your water blank comes up positive, whether it's from the beginning or whether it's from the RNA extraction stage, you need to go back to the tissue and reextract and repeat the process to confirm that that tissue is truly positive. And as part of this, when labs are setting up new TaqMan or PCR assay rooms, they have to be fully knowledgeable about how the flow needs to go. There are many books on it, but if you're doing standard PCR and writing gels, you never take those pipe headers from that room after you clean your area, which is your pre-PCR area. For a confirmatory assay, just to reiterate what Dr. Lanciotti said, there needs to be an independent confirmatory assay.One set of primers may be more sensitive than the other, but we don't know what you're detecting if you keep on repeating that set of primers and saying, "Well we did two assays," when, in fact, it's really one assay repeated. It needs to be two totally independent assays. So, either two sets of primers or an RT-PCR and an IFA or a NASBA—some other totally separate assay. I think that while RT-PCR is wonderful and it's rapid and you can get the results out there, I don't think we should stop trying to isolate virus and cell culture. First of all, you can pick up viruses that the PCR is not specific for. PCR is a very specific assay because of the primers, and with the TaqMan probe, it's even more specific. But, it's important for research to understand the virus and for confirmation that this is an infectious virus to inoculate cell cultures. What does a PCR positive mean? I think we need to try to sort out what's happening with the mosquito pools and the bird tissues as well, where we do see RTPCR-positive tissues that we cannot get out in cell culture. And I think we need to determine how we're going to interpret these.

JOHN T. ROEHRIG: I have a few comments. It's come to our attention that some of you are setting up BSL-3 laboratories in which you want to do plaque assays for serology and also virus isolation. That can be a dangerous approach to take if you're trying to do isolation in the same place that's using standardized West Nile for plaque assays because you're liable to get cross-contamination. Last year when we talked in Fort Collins about the best approaches for RT-PCR, one of the suggestions that we had was that for the plaque assay it may be useful to use a prototype strain like Egypt 101. In our hands it looks as though the New York 1999 strain and the Egypt 101 strain are pretty interchangeable. If you were to use a strain like Egypt 101 in your plaque-reduction neutralization test and happen to get that cross-contaminated into a tissue that you were trying to do isolation from, you could actually tell those viruses apart by sequencing the amplimers by RT-PCR. Unfortunately, at the time, everybody demanded New York 1999, but now that we're a year and a half out, you may want to reconsider how you're doing that plaque assay and go over to something that's actually distinguishable from what you might get from isolates from the environment. My history in arbovirology has been less on nucleic acid and more on proteins and protein structure and function. I just want to remind you that there's another component to viruses besides nucleic acid and it's actually protein that can be used as a confirmatory test. Laura's laboratory uses IFAs on tissues and isolates. There are plenty of monoclonal antibodies available to you that will allow you to identify West Nile and other arboviruses that you may be isolating or seeing. Yesterday, there was a poster on an antigen detection assay that's been developed for West Nile that's as sensitive as the SLE assay. It's been out for a number of years and can be used in tandem either with mosquito pools, or, in this case, it was also shown in tissues of birds, where luckily the virus titers are even higher than in mosquitoes and a relatively good assay. It could be used either as a front-line assay or as a confirmatory assay for other tests. So, be aware that that's out there and should be available to you if that's what you desire to use as well. Later on today or tomorrow, Denise Martin will talk about some of the work she's done looking at the cross-reactivity of IgMs between SLE and West Nile. I'd like to remind you that there are other things out there besides PCR, although PCR is quite good. But, there are other things out there besides ELISAs that you can use to identify antibody reactivities in other species. But you have to be careful when you do things like hemagglutination inhibition assays on birds. The extraction protocols for the sera are a little different than what you may be used to as far as the other nonspecific inhibitors that may be in bird sera that are not removed by the standard sucrose acetone extraction. Bear in mind that there's a lot of literature out there and, you know, one of the implications that's come out of this meeting is that there's a lot of new information that's coming out that people haven't thought about. I think lots of people have thought about these issues for a long time before we've even thought about them. Nothing substitutes for going back and looking at what's been done in the past and seeing how you can apply it to the present and the future.

ROBERT E. SHOPE: Let me first agree completely about the use of Egypt 101 as a strain for neutralization tests for the reason that you're giving but also because I think you'll find that it produces much nicer plaques than the New York strain does. I don't know why, but that's a practical reason to use it. I'd like to make some comments about cross-reactions among flaviviruses. I first learned about the cross-reactions from Jordy Casals, who incidentally just lives down the road here in northern Manhattan, but he described the cross-reactions and flaviviruses using the hemagglutination inhibition test and later using the neutralization test. What happens is that in a primary infection the serological reaction is relatively specific during the first week or ten days postinfection, but then it broadens out and you can use any one of the serological tests against any one of the flaviviruses to show that the person has had a flavivirus infection. As in 1999, it was discovered, even with the capture IgM test, which is relatively specific, that you can misdiagnose closely related flaviviruses. What was called St. Louis encephalitis was really West Nile, and this isn't surprising. This is what one would have expected. I don't have the benefit of working with very many West Nile human sera, and I look forward to hearing the talk tomorrow, but in our animal models—we have an animal model of West Nile—Bob Tesh has developed a model in a hamster that, as far as the clinical syndromes go, is very close to the human picture. About 40% of these animals die following an interperitoneal inoculation. These animals develop a muscle weakness prior to death, and they also develop serological reactions by day six after inoculation; they have rela tively specific antibodies in the hemagglutination inhibition test, and they also start to get IgM. The IgM is gone by day 60, which I think is probably very close to the picture in humans. Is that right?

ROEHRIG: I should have mentioned that. Actually, it goes a little bit longer than that.

SHOPE: OK. But it certainly decreases rapidly just before that time. Regarding the secondary infections, if you inoculate a hamster with yellow fever or Japanese encephalitis virus, follow it and a month later or so inoculate with West Nile virus you get a very brisk anamnestic reaction, which is broadly cross-reacting in all of the tests that we use, so that you need to be careful how you interpret results. Bob Tesh and and his colleagues have been testing human serum in a study collaborating with the Department of Defense using recruit sera from the postal codes zones of the epicenter of the 1999 epidemic. There are no identifiers on these sera. Other than the fact that they're probably eighteen, nineteen, or twenty year olds, we don't know much about them. But we do know where they were recruited from. They're using an HI test, a hemagglutination inhibition test, and many of these sera have positives. Many of the reaction patterns when you test with multiple flavivirus antigens look either like dengue or like multiple reaction sera. These people were bled before they were vaccinated with yellow fever, but some of them may have had prior vaccinations also. So the message here is to be very careful about interpreting serological reactions. A positive with West Nile does not necessarily mean that that person has been infected with West Nile virus. This stimulated us to look at some of our dengue sera. We have four prototype sera that were supplied through Jim LaDuke from dengue patients. There's one from Malaysia, one from the Philippines, one from India, and I forget where the fourth one was from, but we went back and did both West Nile IgM ELISAs on those sera and they're positive, in addition to being positive for dengue. And Bob Tesh also went back and did neutralization tests. Three out of the four sera are positive in the West Nile neutralization test. He uses a 90% plaque reduction, so it's a very stringent test. So, the message is to be careful. In the hamster experiments, we've done a vaccination challenge. The vaccine that Bob Tesh used was the live attenuated Japanese encephalitis vaccine, the vaccine that has been given to millions of horses in China. Those hamsters did not get sick from the vaccination. They were challenged a month later with West Nile virus, and in the controls there was about 40% mortality. There was no mortality in the vaccination challenge test with West Nile virus. So here's an example of a vaccination challenge test that also shows more cross-reaction. There are other implications in the vaccination challenge experiment. I mean it must be obvious to you

that the vaccine for horses used in China probably would be a good vaccine to use for horses in the United States.

MIKE L. BUNNING (Centers for Disease Control and Prevention, Fort Collins, CO): Can I ask John to follow up on the IgM persistence?

ROEHRIG: Sorry, I didn't get that written down on my list. We've been collaborating with the New York City Health Department doing follow-up studies on the longevity of the IgM from some of the patients from the 1999 outbreak, and it's been pretty revealing, although not totally surprising about the longevity of the IgM in some of these patients. Clearly what Dr. Shope said is true: if you look at the IgM response early in infection, and some of these were pretty early infections in 1999, there's a clear spike of IgM activity. This is serum now we're talking about, not CSF. In the early serum infection after 30 to 60 days, it will drop down to lower levels. However, many of these patients carried IgM and continued to carry IgM in their serum specimens above the cutoff level for the IgM ELISA. Not many at this point. I think the last lead was around 500 days postinfection, and at this point the study has been terminated. But it was a very valuable study. What we were interested in looking at and why this was so important from a public health perspective was whether or not IgM could persist from one transmission season to the next at a level that if you happened to have an individual from outside the United States come in with encephalitis the following season, and you did an IgM on them, or something was suspicious of encephalitis, and the IgM was positive but at a lower level, is this truly a recent infection of West Nile or a past infection of West Nile? I think our conclusions are that you actually can be confused by that. That's why earlier on this season, we were recommending acute and convalescent specimens that could be tested as paired sera to actually sort out whether it's an active immune response or if it was a stable older immune response. So it's clear that some patients can carry IgM from one transmission season to the next. Up to this point I think that six months was about as long as this had been investigated, although never with West Nile. With Japanese encephalitis it had been looked at, and actually I guess with West Nile with some of the Romanian patients, Dr. Tsai looked at six-month specimens. So bear that in mind. As people who do serology will tell you, it's clearly always better to have acute and convalescent specimens that you can actually titer. This especially becomes important when West Nile travels into regions where there is more activity from St. Louis encephalitis and you may actually be looking at an SLE infection versus a West Nile infection.

CAMPBELL: So we know now that, at least in a few patients, that IgM would persist for up to a year, and that might have a couple of implications. It goes back to something that Dr. Shope and others have said and that's to be careful because you'd have to imagine a scenario. First of all, a couple of things: the seroprevalence rates in Queens and in Staten Island after the epidemic were quite low. Queens was higher at 2.6% and in Staten Island, less than 1%. So you'd have to imagine a scenario where a person was, say, subclinically infected in the year 2000 in Staten Island and in the next year was unlucky enough to get encephalitis from some other cause and then you test them for West Nile antibody and find IgM antibody. Well, we would not expect that outcome; that would be a very rare event. Second of all, we would not expect that the IgM would persist in the cerebrospinal fluid. Nobody's going to do those studies because they'd be unethical. But at that point when that patient comes into your laboratory like that this summer, you're going to test CSF for one thing and that will help you, but also acute and convalescent serum for development of IgG. So, you've got to look at the whole serological picture in that case. There should be no serious problem in sorting that kind of case out clinically. I think where it has more application or it causes more confusion is in seroprevalence studies where you might have only 1% of people who were infected the year before, and a smaller percentage of those are going to still have antibody later. So, I think it's more of a theoretical concern than a practical impediment. Bob?

SHOPE: From what I've heard this morning, I think there might be a possibility that IgM in the spinal fluid might persist. I have no basis other than seeing some of those pathology pictures.

CAMPBELL: Well, I guess it's theoretically possible, but from what I've heard, persistence of IgM and the CSF would imply that there is active plasma cell production due to ongoing infection of the cerebrospinal fluid. So, from what you saying—from everything we've been able to find in the literature, and Tony Marfin has done a lot of the literature review in this—there's not that much information available. But in the human IgM and CSF it's cleared very quickly, and unless you have active plasma cell production—unless there's a plasma cell that's being stimulated in that sequestered space—the IgM is cleared very quickly. So, that would imply persistent infection to most infectious disease physicians, I think. Maybe you're right. But we'll have to see. I don't know how we're ever going to figure that out, though, because nobody's going to do serial lumbar punctures on patients.

SHOPE: Changing the subject a little bit, I meant to mention that Dr. Hall is here from Australia, and he's developed a test for use in sentinel chickens, which might be more broadly applicable—I don't know. But it might be worth hearing comments from him as to what we really need is a specific serological test, and his approach might be something that's helpful.

CAMPBELL: At this point, we'd invite questions or comments from the audience.

LANCIOTTI: I want to make a quick comment about neutralization, and this is to build on what others, especially Dr. Shope, have had to say. In our lab, when I mention confirmation of the ELISA test by neutralization, that doesn't mean we do neutralization just with West Nile. It's important to do the whole panel of the flaviviruses that occur in North America. So last year we routinely did dengue, because of potential for travel, West Nile, SLE, and Powassan. In most cases when we can demonstrate specific sera conversion to West Nile, the titers to West Nile may have been 1 :512 or greater. There was an accompanying dengue and SLE neutralizing antibody titer much less—1:20 or 1 :40—but I would say in most cases we do see a cross-reactivity, and so I think it's very important when you do the neutralization tests to include the other flaviviruses.

SHOPE: I think it may be important also to test dengue patients, especially the other way around using that same panel against convalescent sera from a dengue patient. And you may find that some of these crosses are more one-way.

DALE L. MORSE (New York State Department of Health, Albany, NY): A number of panel members have mentioned the need for caution in interpreting human serological tests and the need for quality control in confirmatory testing. It wasn't well publicized, but a small number of the laboratories in New York State, New York City, and the CDC last year that had experience with this had some anxious moments as we followed up on screening tests on the serologic IgM that were low level titer or intermediate and as we tracked back to find out whether these really were going to be cases or not. Now as more laboratories are going to come on board, private and commercial, the potential testing that we'll presumably be doing will probably be just a screening test because they don't have BSL-3 or don't have the capability to do neutralization tests. There's a potential for a much larger concern and for following up all these tests or potential reporting of a potential case without confirmatory testing. New York has fairly strong regulations so we can try to have some quality control for those labs coming on, but a number of states don't have that ability to regulate, so I have three questions in this regard. What are the capabilities nationally for quality control of commercial labs that might come on during testing in the coming year? Number two: What is the capability for confirmatory testing for those labs that are going to start showing some potential positive tests on the screening test? And third: Should there be a requirement for a two-step testing before labs can be certified to test for West Nile?

LANCIOTTI: We strongly recommend confirmation by neutralization. Last year, there were a handful of specimens that we couldn't confirm by neutralization. And we're following up on some of those to see what they could have been. But clearly, you need to have a confirmatory test. We would

caution any state from reporting a result without confirmation. Now, if they don't have the ability to do that, that is one of the things that CDC certainly is offering. Many states made use of this where they got a positive IgM, ELISA result, and forwarded the specimens to us for confirmation. If you can't do that in your lab, I think you'd want to have the neutralization tests.

CAMPBELL: I want to ask when MRL [Materials Research Laboratory] may be going to release their test kit for general commercial use.

QUESTION: Well, in theory, they can't because it's not FDA approved, so they could only use a home brew at MRL. So they can't even pass it off as specialty.

LANCIOTTI: We are trying to establish a relationship with MRL so that when they receive specimens—and they have done this—they'll contact us for confirmatory testing. There's also a need for improved communication that's being set up between MRL and the states where the samples came from, because in some cases state health departments are bypassed, where samples are sent directly to MRL and the state epidemiologist is not even aware of it. So, we are trying as best we can to set up all that communication, but certainly MRL is aware, and we have received samples from them for confirmatory testing.

GRADY: I believe New York State also is going to require any laboratory that is permitted to do West Nile testing for New York residents to provide material for confirmation, either at the state laboratory or at CDC, Fort Collins.

ROEHRIG: I think that's a good point. I mean, I think it's kind of a double-edged sword here. It's not necessarily bad to have commercial testing for West Nile because you're casting a broader net to try to find these cases, but somehow the link has to be made for those laboratories to get confirmatory testing. I'm not sure the two-tier testing requirement is going to be the answer because if you do that, it's going to just close out those laboratories that will never do neutralization. The important part is to get the confirmatory testing done somewhere and to make the link back to the state or back to us at the CDC. We can probably do the confirmatory testing. I don't think that's an issue.

[Dr. Duane J. Gubler (born 1939)] **(Centers for Disease Control and Prevention, Fort Collins, CO):** New York is probably one of the few states around that has a system in place where they do actual proficiency testing of local laboratories before they can be certified. And, in fact, do we have a representative here from APHL [Association of Public Health Laboratories]? APHL is really the key to the answer. We went through this with Lyme disease testing, and CDC has no regulatory authority to enforce this kind of proficiency testing. It's really at the state level. We need to bring APHL into this discussion and develop a proficiency-testing scheme probably modeled after the New York program that certifies local laboratories that were testing. And, I agree with John that commercial tests are a good thing as long as they're controlled reasonably well so that there is some quality control. Another solution is to use regional laboratories to do the confirmatory testing. The CDC can't do it all, and New York can't do it all, so we really need to work with APHL to set up regional laboratories to do the quality control confirmatory testing.

THOMAS P. MONATH (Acambis Inc., Cambridge, MA): The requirement to use BL-3 for West Nile and St. Louis and other viruses you'd like to use in performing neutralization tests is an issue for many labs. I'd like to gauge the interest of this group, in particular, on the question of interest in the way of converting these viruses to BL-2 agents so that one could use them safely for neutralization virtually in a large number of labs. Now, the approach that we suggested is to use our chimeric yellow fever technology, which is being applied for attenuated vaccines, so that one would wind up with a family of BL-2 viruses, or basically yellow fever 17D vaccine. But the envelope genes of West Nile, St. Louis, Japanese encephalitis could be used then because they're specifically neutralized only by antibody against each of the respective flaviviruses. They could be used in the neutralization tests to distinguish sera that neutralized a specific virus of interest. So one could actually perform confirmatory neutralization tests in any BL-2 lab with a series of these chimeric flaviviruses that were specific for each of the virus types. Now we already have Japanese encephalitis and West Nile available, and St. Louis needs to be made, and we're willing to undertake that. We're actually working with Dr. Gubler's group now. But it would be useful to know whether this, in fact—if we're going the right direction with this— would be useful. Would it broaden the capability of labs to do confirmatory diagnosis? It might be very useful in the situation of surveillance of birds and other animals as well. It would be interesting to hear some comment from the panel or anybody else in the room to get a sense of how hard to push this, because it would take quite a bit of work to actually validate the technology.

ROEHRIG: For example, with Japanese encephalitis chimera, when you have it approved for human use as a vaccine, clearly at that point that chimera can be classified as a BSL-2 agent. How much characterization do you need to have as far as pathogenesis or virulence in humans before it really will go from a BSL-3 to a BSL-2?

MONATH: Well, we had classified the Japanese encephalitis construct to BL-2 long before human trials.

ROEHRIG: Yes, but that was a vaccine, vaccine chimera.

MONATH: Right.

ROEHRIG: But for West Nile, you're talking about taking a wild type and trying to attenuate.

MONATH: Well, we have mutants now too. They're even more attenuated than the wild-type construct. But, I think the answer is we need data, and there are very good animal models, both mouse and monkey, that can be used. The critical question: Is the chimera less neurovirulent than yellow fever 17D, which is a BL-2 human vaccine? We're testing the appropriate animal system. I think in the case of West Nile, we'll have those data, including monkey data, within a few months. And so at that point what we would do is currently BL-3; we would ask our biosafety, institutional biosafety committee and other collaborators to reevaluate this at BL-2. We might ask the subcommittee, Arbovirus Laboratory Safety, ACAB, to look at this question independently— or the CDC for that matter. But I think it's just a matter of providing the data.

ROEHRIG: So you think preclinical data in monkeys and mice will be enough to downgrade it?

MONATH: Yes.

SHOPE: With Japanese encephalitis virus, is it necessary to use the chimera? The parent of the chimera has been tested in literally millions of humans in China.

MONATH: Right. You could use a vaccine strain.

SHOPE: Yes, the SA14-14-2 strain.

MONATH: We don't have one for West Nile though. There are attenuated strains of St. Louis and you can make the same argument. But I think that the ideal thing is that the yellow fever backbone allows you then to use the yellow fever vaccine for comparison in assessing relative virulence. And so you have a very convincing story about attenuation. So I think for St. Louis and West Nile, that's going to be essential.

SHOPE: I think you make a good case, yes.

ROY A. HALL (University of Queensland, Brisbane, Queensland, Australia): I want to respond to Bob Shope's mention of the competitive assay that I briefly alluded to in my talk yesterday. Basically we designed it for animal surveillance that works quite well for primary infections. We have a batch of sera that CDC had sent to us from New York, and in the initial trial, samples came out positive in the ELISA—not all, but some. And we've yet to compare the data with neutralization tests, and Ann Hunt said she's got the data and we're going to compare them. But at this stage it's still a bit early. It's certainly worthwhile to evaluate it with West Nile.

NANCY HALPERN (New Jersey Department of Agriculture, Trenton, NJ): I have a question for Dr. Shope. You mentioned, I believe, a Japanese encephalitis vaccine for horses. I was wondering if you or anyone in the room might know the mechanism to allow its use while we're waiting for the vaccine's development in this country.

SHOPE: I don't know the proper mechanism, but a great deal is known about the vaccine itself.

HALPERN: I know. I know it's in use for horses, right.

SHOPE: It's also been tested for its ability to infect mosquitoes. Dr. Barry Beatty and Dr. Tenbo Chong did those experiments; they're published. It does not readily infect mosquitoes; since it's alive, the attenuated strains are one of the things you'd be worried about. Maybe someone else knows how veterinary vaccines are licensed.

ALEXANDER E. PLATONOV (Central Research Institute of Epidemiology, Moscow, Russia): What use are the specific ligands for West Nile, for example—not like a physical concentration, but a specific concentration of a sample.

LANCIOTTI: I'm not aware of anyone who has done that with West Nile. So you're saying concentration before one of the nucleic acid tests?

PLATONOV: Yes, for example, or before RT-PCR, before application of any diagnostic tools.

LANCIOTTI: Again, I'm not aware of anyone who has attempted that. I will say that when we use PCR or NASBA or any of those assays looking for West Nile in bird tissues, there is such a large amount of virus that in most cases it's not really a sensitivity issue. There are always going to be a handful of cases where you would like to concentrate before, and mosquito pools are pretty much the same. There's a large amount of virus, so that there are not too many ambiguous samples. It's really in human diagnostics that we run into, I think, an issue either of sensitivity of the test or as likely the timing of the specimen. We're looking at CSF or serum beyond the febrile phase. So there may not be any virus there at all, because we also didn't detect virus by isolation as well.

GUBLER: I want to come back to your point about persistence of IgM antibody in the cerebrospinal fluid, Roy. I know I've read this in Kuno's review of persistence on page nine—I just looked it up. On page nine he says—this is a reference paper published in 1983—monkeys inoculated with West Nile virus presented an asymptomatic infection, but the virus persisted in the brain for up to 5.5 months without viremia. So, in other words, they isolated virus five and a half months after, and so this would explain the persistence of the IgM if this is occurring in humans.

CAMPBELL: I don't remember.

GUBLER: We need to keep an open mind.

CAMPBELL: Did they test cerebral spinal fluid for IgM?

GUBLER: Yes, well they didn't test CSF, or at least he doesn't cover it in here, but it was brain. But indicating that there's virus in the brain meant it may be intrathecal production of antibodies.

ROEHRIG: Well, Duane, I don't think that's a problem, but I think that you're comparing apples to oranges even though monkeys are closer to humans than mice.

GUBLER: I think the point is that we should keep an open mind.

ROEHRIG: Well, I think we should keep an open mind about everything. I don't think that that's an issue. But the point of having cerebrospinal fluid taps, to actually answer the question, is going to be hard to get for humans.

DENISE MARTIN (Centers for Disease Control and Prevention, Fort Collins, CO): I'd like to bring up another point that hasn't been really driven home yet about confirmatory testing. There was a fair amount of concern last year about the length of time it takes to do a confirmatory test in several capacities. There was a lot—especially in states that were looking at the possibility of the first case in their state—of push for doing a neutralization on a very acute specimen last year. And a lot of these extremely acute specimens have not allowed for time for neutralizing antibody to be formed. I think we need to make the point that you can detect IgM by an ELISA test before you can detect IgM in a neutralization test. So, it's extremely important to do a classical neutralization test and see a rise and fall in antibody to get that convalescent specimen. In the push to identify West Nile in each new state, often it doesn't seem to be acceptable to wait for that convalescent specimen, and yet ruling out West Nile on a very acute specimen might be erroneous in the long run.

SHOPE: I think that one could make a case for having a diagnosis that's called a presumptive diagnosis: that's what you do I think. I guess I would be even more conservative, and even after you've done the neutralization test and confirmed the positive reaction that you still call it a presumptive diagnosis, unless you've actually identified the virus either by isolation or by sequencing, because of the cross-reactions that can occur in flaviviruses. I don't know, is anybody else with me on that wavelength? Probably not.

ROEHRIG: I think I missed that.

SHOPE: I don't think we ever have a definitive diagnosis on the basis of serology, and we should keep that in the back of our minds. I understand that the patient and the press demand that you tell them what they have, but we should always, as scientists, keep a little bit of doubt when we're basing our diagnosis solely on serology. That's a personal feeling.

ROEHRIG: So you would say if you had a patient that had presented with clinical encephalitis with muscle weakness, had a huge IgM response in the CSF, and in acute and convalescent specimens showed an 8- to 16-fold titer rise against West Nile encephalitis, and stable or no antibody against the rest of the cross-test as flaviviruses— this isn't a dead person, so you don't have autopsy specimens, and you can't get PCR or isolation positive—that you wouldn't be comfortable that that was a West Nile case?

SHOPE: I would be comfortable on a presumptive basis (general laughter). I think one of the keys to your statement is that you've tested it against all of the other flaviviruses. We continue to find new flaviviruses. In fact, New York City is a case in point; one did find a new flavivirus.

other flaviviruses. We continue to find new flaviviruses. In fact, New York City is a case in point; one did find a new flavivirus.

ROEHRIG: Yes, and as we did the neutralization tests, it became clear that it wasn't St. Louis (general laughter).

CAMPBELL: I want to say one thing: Earlier, Rob Lanciotti used the term "gold standard" in terms of serology, and I think, just to go back to basic principles, most of us would agree that if you're really a purist that the gold standard for the diagnosis of West Nile virus infection is isolation of the virus from the patient, and that's rarely possible. So we all realize that serology is not the same as viral isolation.

GRADY: I should throw in too that we had one case in New York that, based on the capture IgM, was suspect for West Nile, and it turned out to be dengue when the PCR was done on serum. When the folks followed it up, it turned out that it was a travel history; the patient had actually become ill while in Haiti, but didn't bother to seek medical attention until back in New York.

PATRICIA REPIK (Charles River Tektagen, Malvern, PA): This question is for Rob. Are you recommending a virus isolation by any standardized method, say, looking at it for over a period of however many days and doing subpasses, like one subpass or two subpasses? Or is it just plaque isolation? Are you allowing replication to proceed?

LANCIOTTI: There are two ways we do it. For the mosquito testing, we actually just do it with an overlay and look for plaques. But in the human, trying to isolate virus from the human cases, we went the extra mile and did multiple tests and liquid culture and multiple cell lines, and mice, as well. So, we tried everything that we had available to us besides direct mosquito inoculation. I don't think we ever tried that. So, for humans I think that's what we would recommend just because we try everything that is available, not just mammalain cells, but C6-36 cells as well.

ROEHRIG: There's a practical side to this. I mean, we can do that as a reference laboratory, but in the heat of trying to diagnose outbreak at a state laboratory, a local laboratory gets to be a bit tedious when you have a thousand other samples coming in and trying to deal with them. Duane, didn't Bruce do mosquito inoculation with some of those West Nile specimens?

GUBLER: No, unfortunately we didn't do mosquito inoculation, but I think Bruce did show that the fluid culture of Vero cells was probably the most sensitive of the systems. They were all fairly close. Laura and I were just talking about this yesterday. We should do mosquito inoculation in some of these samples. We haven't done them.

HELENE PAXTON: (PanBio InDx, Inc., Baltimore, MD): Rob, at the ASTMH meeting when we had our first West Nile meeting and Duane was chairing it, you talked a lot about using IFA and using slides that had all of the relevant viruses in the United States or outside the United States on your slides so that you could do cross reactivity studies. In the last two meetings, there's been very little said about the usefulness of indirect IFA. As a commercial company, we constantly get barraged with whether you're going to do an IFA titer. Is there any strength in doing, say, a 1:40 screen and a 1:320 screen for each of the viruses that might be circulating in the United States? Can you define any true seropositivity? From what Bob said it sounds like you probably can't, but we do get asked that question an awful lot. The other issue is whether or not, in animal models, if you're doing chickens or horses or some of the other mammals, whether or not the IFA would hold up better. Because most labs—and I'm getting ten or twelve phone calls a day—can't do the more sophisticated techniques, and they want to have a way of screening to see whether or not there's a possibility that West Nile is in the differential diagnosis.

KRAMER: I can answer for use of IFA for bird serology. Susan Wong can answer for the human serology, but we do indirect IFAs on all our ELISA-positive bird sera as the second test, and then if that still is positive we go on and do a plaque-reduction neutralization assay. And it's been very useful in cutting back the number of neutralization tests we need to do, so it's one more refined step after the ELISA. We also use an indirect IFA to confirm positivity in tissues and in cell culture after the cells are inoculated. If cytopathology is seen we spot slides with the infected cells and do IFA on that, and not just for West Nile but for other viruses that are active in New York State.

PAXTON: That's direct FA though, right?

KRAMER: No. Indirect.

PAXTON: You're doing an indirect on the tissues?

KRAMER: Yes. Those were the slides that I showed yesterday and that were in Alan Dupuis' poster.

PAXTON: So you're using positive sera against a substrain as your antigen that could possibly be infected?

KRAMER: We're using the antibody to make sure that what we're seeing is the virus.

PAXTON: I have one other comment. Duane knows this well: the issue of getting FDA clearance. I talked to Woody DuBois at length about this in the microbiology branch, and he is very aware that there is a tremendous need to get these tests cleared. You can't purchase IFA slides as analyte-specific reagents from various manufacturers, and the analyte-specific reagents statute requires that you make a disclaimer in your patient reports saying that this has not been cleared by the FDA. Whole kits have not been cleared and are more problematic, and so you may have a situation where you'll find components floating around where their "label" is ASR. That's really not the intent of the law. But Woody has strongly suggested that if you could get dengue cleared, then West Nile could be treated as a predicate against dengue. If the major problem of West Nile is getting enough samples to be able to do an FDA submission that would hold up, then let's keep that in the back of our minds as we're collecting samples, because a commercial company totally has their hands tied behind their back in trying to get a clearance for an assay without having the proper samples.

ROEHRIG: I think that's a good point. I forget these things, but positive control specimens are really difficult to come by, and luckily over the last couple of years we've had cooperative physicians and cooperative patients, like Dr. Asnis pointed out in her talk, that have been able to donate serum specimens for use as positive control. So for the physicians around, keep this in mind, because this'll be an ongoing need, and you'd be surprised how quickly you go through it. This doesn't include the needs of a commercial company where they need large amounts of these specimens banked.

SHOPE: Let me make a comment. We found that dengue convalescent sera worked beautifully in the capture IgM ELISA for West Nile, and you can get large quantities of that. I don't know whether that would be permitted as a positive control by the

FDA, but they work.

PAXTON: That's the problem, that the dengue is so cross-reactive.

SHOPE: You need to market the test as specific; your test could give you a flavivirus diagnosis, and that would be very useful I would think.

CAMPBELL: Dr. Bresnitz?

EDDY BRESNITZ (New Jersey Department of Health and Senior Services, Trenton, NJ): In the clinical setting where you have a patient who has the right clinical syndrome for encephalitis, and treatable infection has essentially been eliminated, nailing down the diagnosis, when you feel where it's no longer suspect or probable, really has no either clinical or public health practicality to it, to be honest with you. From a clinical perspective, once you nail down the diagnosis it really doesn't make a difference by then. And certainly from the control of mosquitoes it makes no difference either because it takes so many weeks. And I would argue that, in fact, it's what we will do in New Jersey as well: it's letting the mosquito control people know when you have an individual you suspect might have West Nile virus encephalitis—particularly if you're coming from an area where activity has been demonstrated in birds or mosquitoes or horses. That waiting for diagnosis, final diagnosis, or even a probable diagnosis is too late for enhancing mosquito control. So it's a nice theoretical discussion. From a practical perspective it really doesn't make a difference.

LANCIOTTI: We would agree that waiting is probably better, but I can't tell you how many times this year we've gotten calls that said we want you to confirm our ELISA result, and we have a press conference tonight at six. So, that's not uncommon.

SCOTT P. HENNIGAN (Massachusetts State Laboratories, Boston, MA): Is anybody looking into using the Western blot? We use the Western blot for HIV infection; we use it for Lyme in a two-tier method. Is it something that could be used as a quick three-hour—I don't like saying confirmation—but that type test. Instead of waiting for a couple of days for the neutralization, you can actually run a Western blot; you could probably do an IgM or IgG on it also.

ROEHRIG: I come from a laboratory that, before West Nile, dealt with Lyme disease. Where the Lyme disease test is, the Western blot is used as a confirmatory test for Lyme disease, which is, of course, a bacterial pathogen that has multiple antigens. Part of the differential for the Lyme disease Western blot is how many of these antigens are positive, how many are negative, and how many bands are seen. Flaviviruses are fairly simple organisms. There are really three proteins that you can see on a gel, one of which is the M protein, which is a very small membrane-bound protein that is immunogenic, but not overly immunogenic, so you're really looking at two bands on the blot that may actually elicit antibody responses. The nucleocapsid protein, for all viruses and including flaviviruses, is relatively conserved, and so you would get very little serospecificity out of a reactivity with a nucleocapsid. That also needs to be factored in with the nucleocapsid because it interacts with the nucleic acid. It's a highly charged protein and typically gives a very high background in a Western blot. So really you're talking about the envelope glycoprotein as being the most important antigen, and since you're really talking about one band, you can't separate out five or six bands' reactivity patterns. When you talk about the glycoprotein you're talking about other problems with the glycoprotein, which is the confirmational stability of epitopes, whether you run Western blots with mercaptomethanol sulphides or whether you leave it native. The problem is that the protein really isn't big enough to do a lot of differentiation from, let's say, a dengue serum from a West Nile serum from an SLE serum. So I don't think that the Western blot is going to help improve the specificity of the test. We've run a lot of Western blots over the years in my laboratory, and basically this is what you see. I could be wrong, and I want you to keep an open mind, but my best guess would be that a Western blot would not be specific for West Nile infection. A caveat could be that there are also nonstructural proteins that are synthesized by these viruses. A number of years ago, even before I came to CDC, Fort Collins, Dr. Dennis Trent and Ateef Qureshi looked at the immune response as five proteins, and their preliminary evidence was that this was a far more specific protein than the E glycoprotein. The problem with the NS5 protein is that not everybody makes antibody to NS5 to high enough levels that you can detect it on a Western blot. So if you did that sort of thing, you couldn't use virion E (protein); you'd probably have to use infected cells where you'd be looking at the nonstructural or structural proteins. I think that it's a thing that could be used, but we would have to do a lot more work with the specific virus to try to determine whether or not it would be useful. My initial take on it would be that it's probably not going to add much over what we already have.

MONATH: I think the future is going to be very interesting with respect to diagnosis, because, fortunately, so far, West Nile has invaded an area of the United States where other flaviviruses are not so active. But as and if it moves west, West Nile will infect people who previously have seen St. Louis encephalitis. In fact, in the Midwest, there were big epidemics in the mid-1970s. This is the elderly population now that is going to get sick, so the complexity of flavivirus serology, serological diagnosis, is really highest where you have multiple flaviviruses circulating and affecting human population. And the complexities of the patterns of antibodies with respect to cross-reactivity are going to really be problems when this virus appears in the St. Louis country. So I think—if you want to look into the future and prepare yourself for it—that's how that is going to affect our ability to make a specific serological diagnosis. It would be a worthwhile model. We really don't understand very well what happens in these sequential infections to see what happens in the St. Louis–infected animal that's later infected with West Nile. It's going to be a real headache when that happens.

ROEHRIG: Well, at least, Tom, from a public health perspective, if we diagnose it as a flaviviral encephalitis, they can use control and, we hope, try to get it under containment. But yes, actually trying to define exactly what the agent is could be problematic. It will be problematic.

CAMPBELL: It reminds me of something that Dr. Bill Reeves from the University of California-Berkeley reminded Duane and me of recently. Tom, you may know this, but there was some early work—and again, going back to John's point about looking at the early work and trying to appreciate what was already done and not reinventing the wheel; there was some laboratory work done by some scientists years ago, including Dr. Hammon, who is a pioneer in arbovirology—looking at cross-protection of dengue antibodies against West Nile virus in laboratory animals. And there is some cross-protectivity there, and I wonder what we know. I'm not familiar with any similar studies with SLE, but I would suspect there is some cross-protection at least.

SHOPE: There's a large literature on this. Dr. Winston Price did a whole series of experiments in primates. And, yes, there is cross-protection as Tom says.

CAMPBELL: It could be that those people that were infected in Chicago in 1975 are going to be the least likely to get West Nile encephalitis now that they're old.

GRADY: Before we end our panel, I'd like to throw out something else for your consideration: Although West Nile is new, it hasn't replaced the usual causes of viral encephalitis that one sees, particularly enteroviruses and herpes group viruses. And you've got to keep in mind that that has to be part of the differential diagnosis. We have data suggesting that in the same time period in the greater metropolitan and surrounding counties, that there were probably, at a minimum, as many cases due to other viruses as there were due to West Nile. And I say at a minimum because enteroviruses can be recovered by culture, and there are a substantial number of laboratories that have that capability. We don't know what their results were, and likewise more and more labs are coming on line able to do PCR for herpes group viruses. Again, we don't know what their results are. We only know the results of specimens that were tested in our laboratory. Before we leave, I'd like you to remind you to keep that in mind. The outbreak doesn't replace other viruses; it merely is superimposed on what is normally going on.

KRAMER: I wanted to add to that—Dr. Monath reminded me. I mentioned that we do cell culture because we don't want to miss other viruses that are there. And I think it's very important that as this virus moves into Florida, where there's St. Louis, and as it moves toward the West Coast where there's St. Louis, that if people use PCR to look for West Nile in mosquito pools, they might be missing St. Louis. So it's very important to do assays so that you don't miss the other viruses that are there on the mosquitoes as well, because you may not see human cases that will tell you there's another virus there, except that they may be spotty. We don't want to narrow down our focus on West Nile alone, even in the mosquitoes.

may be spotty. We don't want to narrow down our focus on West Nile alone, even in the mosquitoes.

CAMPBELL: OK, it's time to wrap it up. Thank you very much to our excellent= panel.

Thesis *Gas temperature measurements by ultrasonic pulse method* (1955)

Thomas P. Rona (1923–1997) was a 1980s era science advisor to the Defense Department and the White House under Presidents Reagan and Bush.

Born on January 7, 1923, in Budapest, Hungary.[1] Rona graduated from Ecole Superieure d'Electricite (M.E., 1943; E.E., 1945); and Massachusetts Institute of Technology (M.S. in E.E.; Sc.D. in E.E., 1955).[2] He received his license certificate in physical electronics at the Sorbonne in 1946. The author of several books and articles with his best known probably being *Our Changing Geo-Political Premises* published in 1982. Dr. Rona is also credited by some with coining the term of Information War or warfare which he used in a report entitled "Weapon Systems and Information War" delivered to Boeing in 1976. He worked in Seattle, Washington for the Boeing Company from 1959 to 1984. The actual originator of the term "information war" is Dale Minor, a news reporter, journalist and author of the book entitled "The Information War" published in 1970 by Hawthorne Books, Inc.

During the 1980s, Dr. Rona held various posts in the Executive Branch to include Special Assistant for Space Policy at the Department of Defense, 1984 to 1986 and Assistant Director for Government Programs in the Office of Science and Technology Policy at the White House, 1986 to 1987. On June 16, 1987, President Ronald Reagan announced Rona's nomination as Associate Director of the Office of Science and Technology Policy.

In June 1989 he briefly succeeded [**William Robert Graham (born 1937)**] by becoming Acting Science Advisor to President George H.W. Bush, a position he held until President Bush's choice was available in August of that year. When Rona left government service, he did private consulting work in the general area of Information Warfare for companies such as Aegis Research Corporation then headquartered in Rosslyn, Virginia.

Rona died at his home in Bethesda, Maryland, on December 27, 1997, from hypertensive cardiovascular disease.

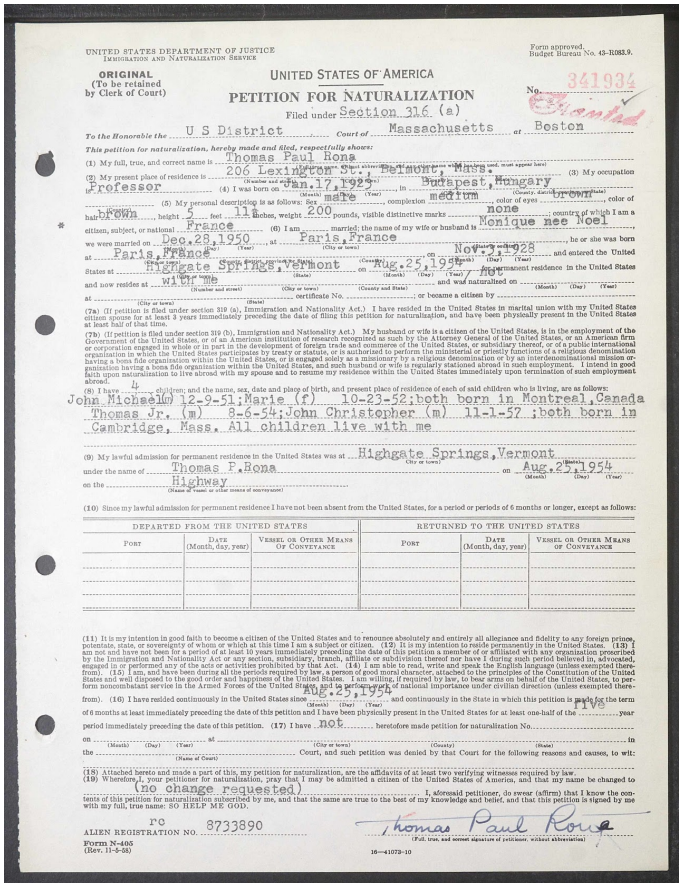
1954 - US Naturalization Petition

Note the name - **Norman Christian Dahl (born 1918)**



UNITED STATES DEPARTMENT OF JUSTICE
IMMIGRATION AND NATURALIZATION SERVICE

Form approved.
Budget Bureau No. 43-R083.9.

ORIGINAL
(To be retained by Clerk of Court)

UNITED STATES OF AMERICA

PETITION FOR NATURALIZATION

No. 341934

Filed under Section 316 (a)

To the Honorable the U S District Court of Massachusetts at Boston

This petition for naturalization, hereby made and filed, respectfully shows:

(1) My full, true, and correct name is Thomas Paul Rona
(Given name) (Middle name) (Family name or surname)

(2) My present place of residence is 206 Lexington St., Belmont, Mass.
(Number and street) (City or town) (County) (State)

(3) My occupation is Professor

(4) I was born on Jan.17,1925 at Budapest, Hungary
(Month) (Day) (Year) (City or town) (County, state, or province) (Country)

(5) My personal description is as follows: Sex male; complexion medium; color of eyes brown; color of hair brown; height 5 feet 11 inches; weight 200 pounds; visible distinctive marks none; country of which I am a citizen, subject, or national France

(6) I am married; the name of my wife or husband is Monique nee Noel

we were married on Dec.28,1950 at Paris,France
(Month) (Day) (Year) (City or town)

She was born on Nov.1,1928 at Paris,France
(Month) (Day) (Year) (City or town) (County, province, or state) (State) (Country)

and entered the United States at Highgate Springs,Vermont on Aug.25,1952
(City or town) (State) (Month) (Day) (Year)

for permanent residence in the United States and now resides at with me
(Number and street) (City or town) (County and State)

and was naturalized on
(Month) (Day) (Year)

at certificate No. ; or became a citizen by

(7a) (If petition is filed under section 319 (a), Immigration and Nationality Act.) I have resided in the United States in marital union with my United States citizen spouse for at least 3 years immediately preceding the date of filing this petition for naturalization, and have been physically present in the United States at least half of that time.

(7b) (If petition is filed under section 319 (b), Immigration and Nationality Act.) My husband or wife is a citizen of the United States, is in the employment of the Government of the United States, or of an American institution of research recognized as such by the Attorney General of the United States, or an American firm or corporation engaged in whole or in part in the development of foreign trade and commerce of the United States, or subsidiary thereof, or of a public international organization in which the United States participates by treaty or statute, or is authorized to perform the ministerial or priestly functions of a religious denomination having a bona fide organization within the United States, or is engaged solely as a missionary by a religious denomination or by an interdenominational mission organization having a bona fide organization within the United States, and such husband or wife is regularly stationed abroad in such employment. I intend in good faith upon naturalization to live abroad with my spouse and to resume my residence within the United States immediately upon termination of such employment abroad.

(8) I have 4 children; and the name, sex, date and place of birth, and present place of residence of each of said children who is living, are as follows:
John Michael(d) 12-9-51;Marie (f) 10-23-52;both born in Montreal,Canada
Thomas Jr. (m) 8-6-54;John Christopher (m) 11-1-57 ;both born in Cambridge, Mass. All children live with me

(9) My lawful admission for permanent residence in the United States was at Highgate Springs,Vermont
(City or town)
under the name of Thomas F.Rona on Aug.25,1954
(Month) (Day) (Year)
on the Highway
(Name of vessel or other means of conveyance)

(10) Since my lawful admission for permanent residence I have not been absent from the United States, for a period or periods of 6 months or longer, except as follows:

DEPARTED FROM THE UNITED STATES			RETURNED TO THE UNITED STATES		
Port	Date (Month, day, year)	Vessel or Other Means of Conveyance	Port	Date (Month, day, year)	Vessel or Other Means of Conveyance

(11) It is my intention in good faith to become a citizen of the United States and to renounce absolutely and entirely all allegiance and fidelity to any foreign prince, potentate, state, or sovereignty of whom or which at this time I am a subject or citizen. (12) It is my intention to reside permanently in the United States. (13) I am not and have not been for a period of at least 10 years immediately preceding the date of this petition a member of or affiliated with any organization proscribed by the Immigration and Nationality Act or any section, subsidiary, branch, affiliate or subdivision thereof nor have I during such period believed in, advocated, engaged in or performed any of the acts or activities prohibited by that Act. (14) I am able to read, write and speak the English language (unless exempted therefrom). (15) I am, and have been during all the periods required by law, a person of good moral character, attached to the principles of the Constitution of the United States and well disposed to the good order and happiness of the United States. I am willing, if required by law, to bear arms on behalf of the United States, to perform noncombatant service in the Armed Forces of the United States, and to perform work of national importance under civilian direction (unless exempted therefrom). (16) I have resided continuously in the United States since Aug.25,1954
(Month) (Day) (Year)
and continuously in the State in which this petition is made for the term of 6 months at least immediately preceding the date of this petition and I have been physically present in the United States for at least one-half of the 1 1/2 year period immediately preceding the date of this petition. (17) I have not heretofore made petition for naturalization No.
on
(Month) (Day) (Year)
at
(City or town) (County) (State)
in the Court, and such petition was denied by that Court for the following reasons and causes, to wit:
(Name of Court)

(18) Attached hereto and made a part of this, my petition for naturalization, are the affidavits of at least two verifying witnesses required by law.
(19) Wherefore, I, your petitioner for naturalization, pray that I may be admitted a citizen of the United States of America, and that my name be changed to (no change requested)

I, aforesaid petitioner, do swear (affirm) that I know the contents of this petition for naturalization subscribed by me, and that the same are true to the best of my knowledge and belief, and that this petition is signed by me with my full, true name: SO HELP ME GOD.

RC 8733890
ALIEN REGISTRATION NO.

AFFIDAVIT OF WITNESSES

The following witnesses, each being severally, duly, and respectively sworn, depose and say:

(1) My name is Dorothy S.Dahl, my occupation is Housewife
I reside at 40 Fern St., Lexington, Mass. and
(Number and street) (City or town) (State)

(2) My name is Norman C.Dahl, my occupation is Professor
I reside at 40 Fern St., Lexington, Mass.
(Number and street) (City or town) (State)

I am a citizen of the United States of America; I have personally known and have been acquainted in the United States with the petitioner named in the petition for naturalization of which this affidavit is a part, since at least Aug. 27,1954
(Month) (Day) (Year)
to my personal knowledge the petitioner has resided, immediately preceding the date of filing this petition, in the United States continuously since the date last mentioned; that the petitioner has been physically present in the United States for at least 21 months of that period; and that the petitioner has been a resident in the State in which the petition is filed during at least the last 6 months. I have personal knowledge that the petitioner is, and during all such periods has been a person of good moral character, attached to the principles of the Constitution of the United States, and well disposed to the good order and happiness of the United States, and in my opinion the petitioner is in every way qualified to be admitted a citizen of the United States.

I do swear (affirm) that the statements of fact I have made in the affidavit to this petition for naturalization subscribed by me are true to the best of my knowledge and belief: SO HELP ME GOD.

Dorothy S. Dahl
(Signature of Witness)

Norman C. Dahl
(Signature of Witness)

WHEN OATH ADMINISTERED BY CLERK OR DEPUTY CLERK OF COURT

Subscribed and sworn to (affirmed) before me by above-named petitioner and witnesses in the respective forms of oath shown in said petition and affidavit, and filed by said petitioner, in the office of the clerk of said court at Boston, Mass.
this 28th day of August, A. D. 19 59

John A. Canavan
Clerk.
By Ruth C. Conway
Deputy Clerk.

[SEAL]

WHEN OATH ADMINISTERED BY DESIGNATED EXAMINER

Subscribed and sworn to (affirmed) before me by above-named petitioner and witnesses in the respective forms of oath shown in said petition and affidavit

at this day of
A. D. 19

Designated Examiner.

I HEREBY CERTIFY That the foregoing petition for naturalization was by petitioner named herein filed in the office of the clerk of said court

at this day of
A. D. 19

Clerk.
Deputy Clerk.

OATH OF ALLEGIANCE

I hereby declare, on oath, that I absolutely and entirely renounce and abjure all allegiance and fidelity to any foreign prince, potentate, state, or sovereignty of whom or which I have heretofore been a subject or citizen; that I will support and defend the Constitution and the laws of the United States of America against all enemies, foreign and domestic; that I will bear true faith and allegiance to the same;

that I will bear arms on behalf of the United States when required by the law;

that I will perform noncombatant service in the Armed Forces of the United States when required by the law;

that I will perform work of national importance under civilian direction when required by the law;

and that I take this obligation freely without any mental reservation or purpose of evasion: SO HELP ME GOD. In acknowledgment whereof I have hereunto affixed my signature.

Thomas Paul Rona
(Signature of Petitioner)

Sworn to (affirmed) in open court, this 15th day of September, A. D. 1959

Clerk.
By
Deputy Clerk.

NOTE.—In renunciation of title or order of nobility, add the following to the oath of allegiance before it is signed: "I further renounce the title of (give title or titles) which I have heretofore held," or "I further renounce the order of nobility (give the order of nobility) to which I have heretofore belonged."

Petition granted: Line No. of List No. 1606 and Certificate No. 6167413 issued.
Petition denied: List No.

1954 (March)- Promotion at MIT

https://wp.technologyreview.com/wp-content/uploads/2012/10/MIT-Technology-Review-1954-03-2.pdf

"Appointments and Promotions: RECENT Faculty appointments and promotions at M.I.T. were announced on February 1 by James R. Killian, Jr., '26. President of the Institute. Promoted to the rank of assistant professor is Vincent J. Roggeveen, '53, a member of the Department of Civil and Sanitary Engineering. ***Thomas P. Rona, '53, has been appointed assistant professor in the Department of Mechanical Engineering.***"

1954/1955 MIT paper : GAS TEMPERATURE MEASUREMENTS BY ULTRASONIC PULSE METHOD

Whole PDF : [HE002L][GDrive]

Look at who was involved :

1. Professor C. Fayette Taylor, Head of the Division of Automotive Engineering at the Massachusetts Institute of Technology (see http://web.mit.edu/hmtl/www/taylor.pdf)
2. Mr. James C. Livengood
3. Messrs E.A. Oster and P.C. Wu
4. Professors [**Dr Jordan Jay Baruch (born 1923)**]
5. Professor **L.L. Beranek** (see https://en.wikipedia.org/wiki/Leo_Beranek)
6. Dr. **T.F. Hueter** - (see https://www.ob-ultrasound.net/hueter.html)
7. **R.H. Bolt** (see https://en.wikipedia.org/wiki/Richard_Bolt)
8. Professor **R.M. Fano** of the Department of Electrical Engineering (see https://en.wikipedia.org/wiki/Robert_Fano ; "In the early 1960s, Fano was involved in the development of time-sharing computers.")
9. Professor **L. Tisza** of the Physics Department (see https://en.wikipedia.org/wiki/László_Tisza - "(July 7, 1907 – April 15, 2009) was a Hungarian-born American physicist who was Professor of Physics Emeritus at MIT. He was a colleague of famed physicists Edward Teller, Lev Landau and Fritz London, and initiated the two-fluid theory of liquid helium.")
10. Mr. J. Caloggero of the Sloan Laboratories
11. The author' s wife, [**Monique R Rona (born 1928)**], contributed to an unusual degree in the creation of the moral and material surrounding which was felt essential in the performance of this work.

ACKNOWLEDGEMENTS

The work reported here has been supported in its various phases by the U.S. Army Office of Ordnance Research and the Coordinating Research Council.

The initiative and supervision of this program was entrusted to Professor C. Fayette Taylor, Head of the Division of Automotive Engineering at the Massachusetts Institute of Technology. (Sloan Laboratories for Automotive and Aircraft Engines.)

The helpful and friendly cooperation and advice of the whole staff of the Sloan Laboratories is hereby gratefully acknowledged. Mr. James C. Livengood has been particularly active with constructive comments and everyday's guidance. Messrs E.A. Oster and P.C. Wu contributed in various ways to test the equipment in actual use on combustion engines.

On the theoretical side, the help given by the Guidance Committee of the Department of Electrical Engineering has been of considerable importance. Professors Jordan J. Baruch, L.L. Beranek Dr. T.F. Hueter and R.H. Bolt contributed generously their time and advices.

In the field of theoretical physics, Professors R.M. Fano of the Department of Electrical Engineering and L. Tisza of the Physics Department allowed the author to draw on their vast background.

Mr. J. Caloggero of the Sloan Laboratories must be credited with resourcefulness in the construction of numerous special measuring devices.

The author's wife, Monique R. Rona, contributed to an unusual degree in the creation of the moral and material surrounding which was felt essential in the performance of this work.

CHAPTER -I-

G E N E R A L I T I E S

1.1 ORIGIN AND NATURE OF THE PROBLEM

1.11 Gas temperature Measurements in Engine Combustion Chamber.

Part of the improvement of internal combustion engine performance in recent years has been brought around by a more detailed and more intimate knowledge of the phenomena which take place in the fuel-air mixture before and during combustion. In addition to other characteristics such as pressure, chemical composition and specific volume, the accurate knowledge of specific temperature in the various phases of the compression stroke has been recognized to be of primary importance for further investigation of fuels and combustion chamber designs.

More specifically, the temperature history of the compression stroke plays a determining role in the engine "knock" which at the present time is one of the factors limiting engine performance. "Knock" or detonation of a portion of the fuel-air mixture before arrival of the "normal" flame front produced by the spark is believed to originate in the rapid compression of the end-gas (portion of the charge last to burn in normal operation) by the pressure rise caused by combustion in the other part of the cylinder.

BIOGRAPHICAL NOTE

The author, Thomas P. Rona was born in Budapest, Hungary on January 17, 1923. Raised and educated in Paris, France, has obtained the degree, Mechanical Engineer in 1943 (Ecole d'Electricite et Mecanique Industrielle, Paris), the degree, Electrical Engineer in 1945 (Ecole Superieure d'Electricite) Paris, and the Certificat d'Etudes Superieures, Electricite Generale (Sorbonne, Paris) in 1945.

His professional carrier includes the French Thompson Houston Co (Radio transmitters) the French National Office for Aeronautical Research (wing vibrations and Analog Computers) and a Consulting Engineer Practice in the French Equatorial Africa (Civil Engineering and Hydro-Electric Power Plant Sites).

In 1951, the author came in Montreal, Canada, as Assistant Professor of Electrical Engineering at the Ecole Polytechnique of Montreal. He joined the Massachusetts Institute of Technology staff in 1952, where he obtained the degree of Master of Science in Electrical Engineering in 1953. Currently holds the appointment of Assistant Professor of Mechanical Engineering at the Institute.

His family includes his wife, Monique R. Rona-Noel, and three children, John-Michael (1951), Marie-Helen (1952) and Thomas Paul Jr. (1954)

Like Your Neighbors

Wives Of Scientists Friendly, Interesting Folks

By VIRGINIA CHAPPEL
Times Correspondent

Alamogordo, N. M.—Wives of top scientists in the United States, who are spending this summer in Cloudcroft for consultation, are just friendly and unassuming as your next-door neighbor.

They lead about the same lives as other wives. They keep house for their husbands, prepare their meals, bear them children. Like most other wives, they know little about their husband's work.

Perhaps the greatest variance in the daily routine of these women with that of their feminine contemporaries is their opportunities for travel. Being married to top brains in the field of science takes them on many special trips, such as the one to Cloudcroft.

These women are Mrs. Knox Millsaps, whose husband is director of the consultations, and Mrs. Spiro Kyropoulos, both of Pasadena, Calif.; Mrs. Paul R. Rider, Dayton, Ohio; Mrs. Joe R. Foote, Norman, Okla.; Mrs. Frank W. Bubb, Webster Groves, Mo., and Mrs. Stephen Crandall, Lincoln Mass.

Two other scientists in the group are bachelors. They are Sigurd Hoyer of Oslo, Norway, a graduate student from Massachusetts Institute of Technology, and Dr. Alfred Simon of San Luis Obispo, Calif.

Another scientist and his wife, Mr. and Mrs. Thomas Rona of France, who have been at Cloudcroft, have returned to Belmont, Mass.

With the exception of Mrs. Millsaps, this is the first trip to New Mexico for the women. Mrs. Millsaps, the former Miss Lorraine Hartle, Pasadena teacher, last year visited in the area before she was married to Dr. Millsaps.

All of the women are fascinated with the Southwest. They say their husbands feel the same way about the country, and the entire group is determined to visit as much of the area as possible, before returning this fall to their homes. They do things as a group and already have had a moonlight picnic at the White Sands, seen the Carlsbad Caverns, visited El Paso and Juarez.

The wives agree, in unison, that being married to well-known scientists seems to induce everyone to make them feel "at home," wherever they go. Mrs. Millsaps, who has studied at the National University in Mexico City, says, "everyone is so nice and solicitous."

At home, the women say, "our husbands take us for what we are and let it go."

"The men's work is so strenuous and demands such great concentration, they just want to relax when they get home," says Mrs. Bubb, who is interested in civic affairs and belongs to the League of Women Voters.

"When the group gets together at night," says Mrs. Rider, a talented pianist, "we just have a good time, and there is a lot of humor in the talk, with no mention of the Geophysical Year, statistics or space, despite the fact that each one of our husbands is an expert in some field of science."

Mrs. Riker and her husband are close friends of the Harry Trumans. They have spent a year in London, where Mrs. Riker continued her music studies, and a year in Mexico City.

Among the group, Dr. Kyropoulos, a former German university professor, holds quite a reputation for telling good stories. Mrs. Kyropoulos says she has heard them often, but they are still good tales. Now a U. S. citizen, she used to write children's stories when she lived in Leipsig, Germany. Her stories were about princesses, queens and kings, she explains, and when the Communists came, they made her give up her writings. She and her husband came to the States in 1948.

A favorite hobby of Mrs. Kyropoulos' is biology, in which Mrs. Bubb also is interested. They have found the Cloudcroft area an ideal site for pursuing this, and say they have found many native flowers in the mountains which even their wildflower books do not identify.

Mrs. Foote, mother of three young children, says she hasn't much time right now for hobbies, but she and her husband always join in social activities of the group. In Norman, she is active in the Woman's Society of Christian Service and other Methodist church activities.

Often, when the scientists and their wives are together, Mrs. Stephen Crandall adds a bit of song. She possesses a fine voice.

All the six wives take turns doing small social favors for the two bachelor scientists. They keep various tinned foods on hand for impromptu occasions.

"Our main social events," says Mrs. Riker, "are drop-ins."

These informal events keynote the overall pace of the gathering this summer at Cloudcroft, where top scientists are discussing great problems amidst a picturesque New Mexico setting.

CLOUDCROFT VISITORS—*Informal visiting is enjoyed by scientists' wives who with their husbands are spending the summer in Cloudcroft. Standing are, from left, Mrs. Knox Millsaps, whose husband of Massachusetts Institute of Technology is directing the scientists consultations; Mrs. Paul R. Rider, Dayton, Ohio; Mrs. Frank W. Bubb, Webster Groves, Mo., and Mrs. Joe R. Foote, Norman, Okla. Seated is Mrs. Spiro Kyropoulos, Pasadena, Calif.*

Research in Mechanical Engineering

- Research continued on a large scale throughout the year and is becoming one of the principal means of education of graduate students. A partial and necessarily incomplete narrative of these researches, which have given rise during the year to fifty-five published scientific and technical papers, three books, and thirteen Sc.D. theses, follows.
- Professor Tau-Yi Toong has been working on theories of ignition and flame stabilization under a grant of the National Science Foundation and is conducting research on the interactions between burning fuel droplets under a grant of the Shell Oil Company.
- Professor Frank A. McClintock, in his studies on the mechanism of fracture in metals, has made a theoretical analysis of the stress and strain fields around a crack and has succeeded in establishing criteria for failure from this theory which agree with experiments on the behavior of aluminum foil.
- **Professor Thomas P. Rona is working on the development of a magnetostrictive ring oscillator and on a bifilar inertia reference system with optical registration, both of his invention. He and Professor Crandall have embarked on research on random vibration processes, which recently have acquired great practical significance. They also have taken part in an Air Force development of a highspeed carriage (up to Mach 10) on a track of several miles length.**

3,146,057

VIBRATILE TRANSPARENT FILAMENT ACCELEROMETER

Thomas P. Rona, 614 Hazel St., Kent, Wash.

Filed May 8, 1961, Ser. No. 108,458
6 Claims. (Cl. 346—108)

The present invention relates to an accelerometer capable of indicating an abrupt motion disturbance in a wide variety of applications by the pattern of light transmitted axially through a transparent filament.

A principal object is to provide such an accelerometer which is very light, small and compact, yet which can produce an indication which is readily visible or can be recorded easily by very simple apparatus.

A further object is to provide mechanism associated with the accelerometer which can make a record of movement of the acceleration sensitive element in various ways, such as on a stationary film, or on a moving film or in a numerical record.

It is also an object to provide an accelerometer sensitive to different types of disturbance such as vibration, shock, impact, static electricity, or magnetic forces.

Such objects can be accomplished by an accelerometer in which a vibratile transparent filament is supported in cantilever fashion having its supported end exposed to a source of light in close proximity to it for projecting light axially through the filament irrespective of the deflection of its free end. The light transmitted by the filament is directed through a magnifying and focusing lens system, or objective onto an indicating or recording surface, such as a ground glass for observation or a film or photoelectric device for recording.

FIGURE 1 is a top perspective of the accelerometer with the near quadrant broken away to reveal its internal construction.

FIGURE 2 is an enlarged central longitudinal section through the accelerometer.

FIGURE 3 is an enlarged fragmentary longitudinal section through the filament-supporting and illuminating portion of the accelerometer.

FIGURES 4, 5 and 6 illustrate sections of film bearing representative traces made by light emitted from the accelerometer filament.

From the drawing it is difficult to appreciate the small size of the accelerometer, but it should be kept in mind that the entire length of the accelerometer body shown in FIGURE 1 would be only about two and one-half inches and the outside diameter of the assembly shown in that figure would be about one inch. This accelerometer assembly conveniently can be mounted in a threaded aperture in a mounting wall **1** so that it can be removed and replaced readily. The assembly thus mounted in the wall will enclose completely the sensitive, or fragile, parts of the accelerometer so that they will be protected from damage. The accelerometer assembly may, however, be taken apart readily for repair or replacement of parts.

The accelerometer assembly includes a barrel **2** having a thick wall as compared to the entire size of the accelerometer assembly. A stepped bore extends through this barrel which has a central portion **3** of smallest diameter forming a chamber in which the delicate transparent filament **4** is received. This filament may have a total length of approximately three-quarters of an inch with approximately two-thirds of its length being free and supported in cantilever fashion by the other third of the filament length being secured in a mounting plug **5**. The exterior of this plug is stepped and the smaller portion adjacent to the free end of the filament is threaded to screw into a complementally threaded end of the central section **3** of the bore through the barrel **2**.

The vibratile linear filament **4** is of bendable and resilient, in other words limber, transparent material, as indicated in FIGURE 3, having a diameter of the order of one-thousandth of an inch and having light refraction characteristics such that a beam of light will be emitted from one end when the opposite end is illuminated irrespective of the amount or nature of the deflection of parts of the filament between its ends. Such light-conducting filament may be a single glass fibre, for example. The core of the filament will have a high index of refraction and the surface of the filament will have a low index of refraction so that light is trapped in the filament instead of being emitted along its length. The supported end portion of the filament can be embedded in wax or resin **6** in the bore of the plug **5**, but the supported end of such filament will extend completely through the wax body so that the end of the filament will be exposed in the cavity **7** in the base of the plug communicating with the plastic filled bore in which the filament is mounted. Care should be taken in mounting the filament in the plug bore so that, as shown in FIGURES 2 and 3, the free end portion of the filament when at rest will extend substantially coaxially through the bore of chamber **3**.

The base of the plug **5** is received in an enlarged portion **8** of the bore through the barrel extending from the smaller central portion of the bore to one end of the barrel. This enlarged portion of the barrel is closed by the cover **9** having a boss fitting within such enlarged bore portion. This boss has a central tapped aperture constituting the socket for a miniature light bulb **10** having a threaded base adapted to be screwed into such socket. The length of the enlarged bore portion **8**, the axial extent of the boss on cover **9** and the axial extent of the cavity **7** in plug **5**, are proportioned relative to the length of the light bulb **10** so that, as shown best in FIGURE 3, the end of the light bulb will be in very close proximity to the supported end of the filament **4**. When the light bulb is energized, therefore, a maximum amount of light will be projected into the supported end of the filament.

The light bulb **10** may be of the center contact type so that one circuit connection will be to the barrel assembly generally. The other contact **11** of spring strip type can be mounted suitably on plate **12** and connected to a wire **13**. Such plate and the cover **9** can be secured to the end of the barrel by bolts **14** screwed into tapped holes in the end of barrel **2**.

In the end of the barrel **2** opposite the light source, the bore through the barrel is enlarged to form the cavity **15** having an internally threaded portion adjacent to the end of the barrel. Into this cavity is screwed an objective **16** providing a lens system which will magnify and focus the beam of light emitted from the free end of the filament 4. Such objective can be secured in place in the barrel by the recessed set screw **17** received in a threaded aperture in the barrel **2** extending transversely of its length and located farther from the open end of cavity **15** than the extent of the threaded portion of such cavity.

The barrel **2** must be mounted in proper relationship to an indicating or recording surface on which the objective **16** focuses the light beam emitted from the filament **4**. Consequently, it is convenient to mount both the barrel and the support for the indicating or recording surface in proper relationship to the mounting wall **1**. A tube **18** secured to one face of the wall by screws **19** threaded into tapped holes in the wall may be supported in alignment with an aperture **20** extending through the wall to receive the accelerometer assembly. On this tube is mounted the desired indicating or recording medium, such as a ground glass or a film to receive light from the objective **16**.

As representative of a film holder as typical of a recording medium, the film case **21** is shown mounted on the end of tube **18** remote from the wall **1**. Opposite ends

Section 5
PANEL SESSION

THE ESTABLISHMENT OF TEST LEVELS FROM FIELD DATA

Moderator: Professor Charles E. Crede
California Institute of Technology

Panelists: Mr. Maurice Gertel
Allied Research Associates, Boston
Mr. Neal Granick
NASA, Goddard Space Flight Center
Dr. Thomas Rona
Boeing Airplane Company, Seattle
Dr. Robert Mains
General Electric Company, Schenectady
Dr. Allen Curtis
Hughes Aircraft Company, Culver City

Those concerned with determining the probability that a given equipment will fail in service are faced with the problem of translating environmental data into realistic laboratory tests. Simulation is the art of laboratory testing to create a condition that is representative of the actual environmental condition to which equipment will be subjected. In this context, a simulated environment is not necessarily similar to the actual environment but rather has the same damaging potential. Various criteria of damage have been proposed to evaluate this damaging potential. These, together with analytical and empirical techniques for establishing laboratory test levels were considered by the panelists and form the subjects of the prepared presentations. In presenting the general discussion which followed, a verbatim transcript has not been attempted, but comments have been condensed and consolidated under a number of general headings.

OPENING STATEMENT OF THE MODERATOR

Dr. Crede

This panel has been assembled (1) to present a cross section of the latest thinking on the problem of establishing test levels from field data and (2) to give members of the audience an opportunity to obtain comments on their problems from the experts on the panel. I have deliberately avoided saying that the experts will answer your questions because there are no known answers to many questions that can be asked.

Essentially everyone engaged in the design or manufacture of equipment for military use has a problem in determining test conditions. The very stringent requirements for reliability of such equipment dictates that the equipment should be subjected to shock and vibration tests in the laboratory. The objective of such tests is relatively easy to state: The laboratory tests should cause all failures and malfunctions that would later occur in

[HC0046][GDrive]

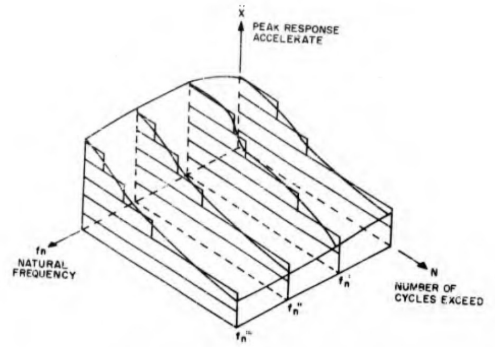

Fig. 3 - Three-dimensional shock spectrum

I must point out, however, that there is a class of equipment failure, described as "temporary malfunction," e.g., electrical noise, loosening of fasteners, etc., for which the presented data reduction technique doesn't fully apply. This isn't a major handicap, however, and until we find a way to design tests for malfunctions the present method based on simulating structural damage will ensure the structural integrity of the equipment we place in future vehicles.

Dr. Crede

Now, if we have followed the advice of Dr. Curtis and Mr. Gertel, we will have separated out from the complexities of a time-history certain numerical parameters which indicate the nature and severity of the field conditions. From our knowledge of these field conditions, we can determine the over-all time during which the equipment will be subjected to these conditions. For example, equipment installed in a manned aircraft may be required to endure hundreds or thousands of hours of vibration, whereas that installed in a ballistic missile must withstand only a very few minutes of vibration. Finally, we may know something of the nature of the equipment to be tested which can be applied in selecting appropriate tests. Dr. Rona, if you were supplied with reduced data as outlined by Dr. Curtis and Mr. Gertel, together with the other information that I mentioned, what concepts would you apply in devising a laboratory test to best simulate the field conditions?

TEST PROGRAM BASED ON MEASURED ENVIRONMENT

Thomas P. Rona

The question, as phrased, may imply that the only thing I can use is the data supplied by my copanelists. Actually, what I shall try to do is to limit the proportion of the test designer's judgment which enters into the definition of the test, and attempt to increase the rational elements. We should not delude ourselves by thinking that by rational we mean absolutely incontrovertible. It is simply a matter of where the elements of judgment do come in the picture.

Specifying a rational shock and vibration test program is, in general, impossible on the basis of measured environment only. While "environment," translated as meaning here input and output phenomena connected with

[HC0047][GDrive]

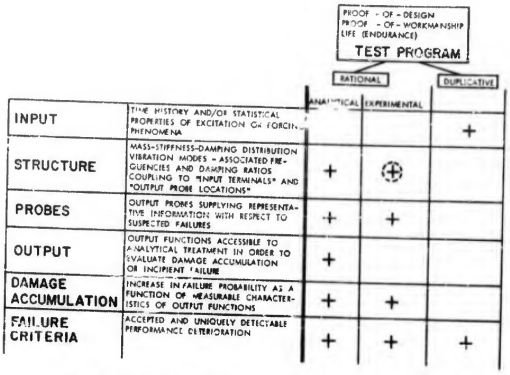

Fig. 4 - Proof of design, workmanship, and life (endurance) of "rational" and "duplicative" test programs

vibration and shock, is one of the essential ingredients of such rational test programs, other information types are just as indispensable. Figure 4 characterizes the components of what may be thought of as being an ideal situation. Two "rational" test program determination processes are compared with a "duplicative" process in order to illustrate the specific requirements of both types.

Before examining the detailed nature of such requirements, the following preliminary statements should be clearly spelled out:

Practical considerations of operational nature often do impose constraints that dominate the technical considerations discussed here. It cannot be our purpose to conceive methods that would modify the respective weights given to operational and technical constraints.

Certain items of information about the type of equipment to be tested (among others, the safety factors, mission success probability and performance penalty paid for overdesign) will often supply valuable indications in order to decide between "rational" or "empirical" test programs.

The objective pursued here is to clarify the differences in input requirements and in quality of test results expected rather than to take a definite stand in favor of one or the other of the approaches discussed.

Figure 4 shows proof of design, proof of workmanship, and life (endurance) test programs in two categories. "Rational" test programs are the ones which, presumably, would start from all the available necessary information in order to obtain results with a minimum of equipment and effort. For want of better description, we call "duplicative" the type of test performed when only the shock and vibration input characteristics to a given piece of equipment are known together with some arbitrary failure criteria. Our efforts are exerted toward duplicating inputs as accurately as possible in order to produce, hopefully, identical failures.

The horizontal lines represent types of information necessary to design test programs. These types are:

Input quantities, in our terminology, are time-history and/or statistical properties of excitation or forcing phenomena. When vibration and shock inputs are not transmitted through specific mounting points, the spatial distribution of input phenomena is also required.

[HC0048][GDrive]

For structure, ideally, the information needed is that which would lead to a complete, detailed dynamic history of the whole structure (including its smallest component) under any arbitrary vibration input. It is clear that such complete information would never be available; however, mass stiffness and damping distribution, possibly the vibration modes (normal or not), associated natural frequencies and damping ratios, as well as the relationship between these vibration modes and excitation input terminals and measuring probe locations are of importance. As a matter of practical limitation, the degree of resolution that is necessary for the knowledge of the structure is determined largely by the shortest "wavelength" that is conceivably present in the structure.

Under the heading "probes," we mean accelerometers, displacement meters, velocity meters, strain gages, strain indicators, and, in general, any device which will give information with respect to the absolute or relative motion of one portion of the structure. As stated above, the information required includes relation of the output probe indications and the structural motions. In addition to this, it is necessary to be in position to relate probe indication with respect to suspected or expected failures.

The output function, in certain cases, must satisfy a certain number of analytical conditions in order to evaluate damage accumulation or incipient failure threat. A typical example would be that a random vibration environment is required to be Gaussian and reasonably narrow band before a meaningful prediction of amplitude distribution probability or peak distribution probability can be made on an analytical basis.

Damage accumulation is the process serving at the base of our prediction that the failure probability of a given structure or subassembly will increase monotonically with the duration of shock and vibration history. The small number of damage accumulation concepts now available should not prevent us from recognizing that they are central to the whole idea of rational test program planning.

Finally, failure criteria are necessary in order to establish a clear-cut end point for failure test programs. Such criteria are quite evident when physical rupture of structural components are involved; they are, however, not so obvious when failure is a function of performance deterioration of electronic equipment, or of a change in temperature, chemical structure, etc.

Figure 4 also illustrates the role of these various input data categories with respect to test program planning. It is readily apparent that if by "environment" we mean shock and vibration input phenomena these are only required for duplicative programs. They are not essential (and possibly not even useful) to the so-called "rational" processes.

If the measured output is of sufficiently simple form to allow analytical application of the available and accepted damage accumulation formula, and if, further, the measured output is uniquely related to the expected failure(s) the test program is described without difficulty in principle. The practical application of such a process, however, is a matter of some complexity (Fig. 5).

DIFFERENTIAL MAGNETOMETER HAVING PARALLEL ROTATING FIELDS AND ASSOCIATED SENSING CIRCUITRY

Thomas P. Rona, Seattle, Wash., assignor to The Boeing Company, Seattle, Wash., a corporation of Delaware

Filed Sept. 14, 1966, Ser. No. 579,423
Int. Cl. G01r 33/02; F42b 23/26, 21/00
U.S. Cl. 324—43 **10 Claims**

ABSTRACT OF THE DISCLOSURE

The present invention relates to an improved differential magnetometer for measuring gradients in a magnetic field. First and second core assemblies are displaced along an axis and energized by in-phase rotating magnetic fields which are perpendicular to the axis. Elongated ferromagnetic rods are disclosed as being aligned in two parallel planes with the rods secured to the central cores and being provided with windings for generation of the rotating fields. First and second sensing circuits respectively coupled with cores provide first and second output signals which are compared to provide an indication of any perturbation of one rotating field relative to the other. Mechanical and electrical details of a preferred embodiment are provided.

Magnetometers have found widespread uses in recent years and particularly in connection with the detection of surface ships, submarines and other magnetically susceptible objects in the water. Magnetometers (or gradiometers) in particular found widespread usage in floating mines as well as in the detonating devices of torpedoes. As a result of the effort expended in the field of magnetometers a relatively large number of such devices are now available making use of various phenomena such as changes in reluctance of a magnetic circuit, proton resonance, or modifications of optical and/or microwave characteristics of various vapors. While such instruments have met with success and have been produced at various costs and having varying sensitivity levels, it is found that most such instruments measure either the so-called "component field" so that the instrument must be carefully stabilized, or that the instrument is adapted to measure total field in which case it is substantially non-sensitive to direction. In instruments of the first type the direction of a magnetic field along a preferential axis of the instrument is measured and therefore if minute changes of direction of the instrument occur such are interpreted as modifications of the magnetic field and hence false indications are generated unless the instrument is very carefully stabilized. While instruments of the second type which measure total field do not have the problem of false signals caused by changes in direction of the instrument, it is found that such instruments will not measure deflections in the magnetic field without change in magnitude.

It is therefore an object of the present invention to provide an improved magnetometer which is insensitive to moderate changes in attitude and direction. Another object of the present invention is to provide a magnetometer which measures any change in magnitude or in direction of the field gradient. An additional object of the present invention is to provide a differential magnetometer which is insensitive to moderate changes in attitude and direction and yet which measures any change in magnitude or in direction of the field gradient without the need for expensive attitude control equipment. Another object of the present invention is to provide a magnetometer having directional sensitivity without the need for high instrument stability in terms of physical location

2

within the field. A more specific object of the present invention is to provide an underwater differential magnetometer for detecting changes in magnetic field gradient caused by the presence of a ship.

In accordance with the teachings of the present invention the above advantages and objects are achieved through the use of a pair of magnetic core assemblies located at opposite ends of a rigid beam. The planes of the core assemblies are maintained parallel with each being perpendicular to the beam. Each core includes a plurality of ferromagnetic rods with the various rods in the two core assemblies being parallel with their respective counterparts within manufacturing tolerances. Each rod extends through the center of the core assembly so that pairs of rods are provided in each core. Each such pair of rods is provided with excitation coils which are energized by an oscillator in unison in a manner such that a rotating excitation field is provided for each core with the field rotation for the two core assemblies providing a bias field rotating at a first frequency.

In one system each core assembly has three rods so that a regular hexagonal system of magnetic axes is provided for each core assembly. The shape and configuration of the core and rod assemblies is such that an external field in the plane of the core assemblies induces within each core a magnetic field which is essentially proportional and parallel to such pane at the location of each core. When the cores are maintained with their planes substantially paralled to the earth surface the external field is that which would be generated by the superposition of the earth's magnetic field and a submarine dipole field when the magnetometer is disposed in the ocean.

Each core is also equipped with a multiplane common-mode impedance measuring circuit. In the specific example illustrated wherein a hexagonal arrangement of core rods is utilized a tri-phase common-mode impedance measuring circuit is utilized. Thus a hexagonal "spider" arrangement of sensing coils and laminated pole pieces is provided for each core assembly. The test coils of these "spider" assemblies form part of an impedance measuring circuit which is driven at a frequency much higher than the bias field frequency. Thus through the use of a tuned bridge circuit arrangement the impedance difference between the two core assemblies is measured to a very high degree of accuracy. Due to the non-linear induction vs. magnetic excitation characteristics of the core material, the measured impedance of each test coil is a very sensitive function of the magnitude of the magnetic excitation resulting from the superposition of the artificially induced bias field and the external field, i.e., the earth's magnetic field including possible local perturbations such as the one caused by the passage of a ship or submarine. If the external perturbation is not identical (in magnitude or direction) for both cores, the difference will be translated in a measurable impedance difference. Thus the output signals provide an accurate indication of any change in the magnitude or direction of the magnetic field gradient.

These and other aspects of the present invention will be more clearly understood from the following description when read with reference to the accompanying drawings wherein,

FIGURE 1 is an isometric drawing with portions cut away from the casing for one specific type of magnetometer provided in accordance with the present invention for underwater use in detecting submarines,

FIGURE 2 is a drawing of the magnetometer of FIGURE 1 located beneath the surface of the ocean and showing a submarine approaching the magnetometer,

FIGURE 3 is an end view of one core and spider assembly of the magnetometer shown in FIGURE 1,

[HG007W][GDrive]

3

FIGURE 3A is a cross-section along the lines 3A—3A of FIGURE 3 showing the construction details of one core and spider assembly, and

FIGURE 4 is a schematic circuit diagram of one bias field and sensing coil circuit adapted for use in the system of the present invention.

Referring now to the drawings and in particular to FIGURE 1 an underwater embodiment of the differential magnetometer of the present invention is shown. The apparatus includes a pair of magnetic core and detector assemblies **10** and **11** having their planes maintained parallel to each other by being firmly secured to a rigid beam **12**. The core and detector assemblies are disposed within an elongated tubular housing **13** held in a substantially vertical position by means of an air compartment **14** in the upper end thereof and an anchor and connecting cable assembly **15** and **16** at the lower end thereof. A signal transmission cable **17** extends through the upper end of the housing **13** and has its upper end maintained above or in the vicinity of the surface of the ocean by a suitable flotation device **18** (FIG. 2) so that the information provided by the magnetometer can be transmitted to a remote receiving station by any conventional radio or acoustic transmitter means. The core and detector assemblies **10** and **11** are held in position in the casing **13** by means of the springs **19** and **20**, respectively, spring **19** being secured to the bottom of the air compartment **14** and spring **20** being secured to the electronics package and ballast compartment **21** in the lower portion of the casing. The internal pressure within the casing or housing **13** is preferably vented to the outside with the arrangement being such that when the assembly is anchored in place and stabilized by such purely passive means the longitudinal axis of the instrument will not depart from the vertical by more than 10°. With the instrument located beneath the surface of the ocean as seen in FIGURE 2, and with the axes of the core and detector assemblies being located as shown, the equipment will be sensitive to the vertical gradient of the horizontal component of the earth's magnetic field having the dipole field of a submarine **22** superposed thereon.

Referring now to FIGURE 3 the construction details of one preferred embodiment of the core and detector assemblies will be described. As seen in FIGURE 3 each core assembly includes three ferromagnetic rods with each of said rods having two sections extending in diametrically opposed directions from the central core piece. Thus the sections **31A**, **31B** in effect provide one rod, sections **32A** and **32B** another rod, and **33A**, **33B** a third rod with each extending perpendicularly from the outer surface of the cylindrical laminated core piece **34**. Each rod end is provided with an excitation coil **35A**, **36A**, **37A**, **35B**, **36B**, and **37B**, respectively. Each pair of coils **35A–35B**, **36A–36B**, **37A–37B** is connected with the two coils of the pair in series. The arrangement is such that a triphase system of excitation coils is provided for each of the three rod assemblies in the two core assemblies **10** and **11**. The rods in the two core assemblies **10** and **11** are parallel to their respective counterparts with the excitation coils being connected such that each pair of rods (i.e., one rod from assembly **10** and one rod from assembly **11**) is provided with an in phase excitation signal. Thus a triphase excitation system is provided for each of the two assemblies with the excitation being "in phase" for the two. In order to show the manner in which the core rods are aligned it will be seen in FIGURE 3 that the core rods **31**, **32**, and **33** for the assembly **10** are broken away near their outer ends so that the rods **41**, **42** and **43** together with their associated excitation coils **45**, **46** and **47** will be seen in exact alignment therewith and forming part of the core assembly **11** of FIGURE 1.

The arrangement will be seen to be such that each core and rod assembly allows an external field in the horizontal plane to induce within the core a magnetic field which is essentially proportional and parallel to the

4

external horizontal field component at the location of each core. In addition, as seen in FIGURE 3 (and in FIGURE 4 to be described hereinafter) the excitation windings and associated three phase generator cause a constant arbitrary magnitude bias field to be superimposed upon the external field with the said bias field rotating in the plane of the cores with respect to the core orientation and at an angular velocity determined by the frequency of the excitation oscillator.

As seen in FIGURES 3 and 4, each core assembly includes a triphase common-mode impedance measuring circuit. Thus a hexagonal "spider"-shaped reluctance pickup frame **50** will be seen in FIGURES 3 and 3A to be disposed about the core **34**. Each of the six legs **51** of the member **50** are cemented to the exterior of the core **34** along the line of contact **50A** seen in FIGURE 3A. Each of the six legs **51** also has a separate sensing coil **52** disposed thereabout so that the impedance of the central core member **34** can be measured at the fercuency of the measurement signal oscillator **70** shown in FIGURE 4 connected to each of the sensing coils **52**. The arrangement of the parts in the lower assembly **11** of FIGURE 2 is identical to that shown in FIGURES 3 and 3A for the upper unit **10**.

To protect the various components in each of the core and detector assemblies a protective ring of nonmagnetic material **55** is preferably cemeted to the ends of the rods as shown in FIGURE 3.

Referring now to FIGURE 4 the details of one specific embodiment of the circuit arrangement for the system of the present invention will be described. A three phase oscillator **60** denoted as operating at ten cycles per second will be seen to be connected by its three output leads **61**, **62** and **63** to the excitation coils **35**, **36**, **37** and **45**, **46** and **47** through the filier coils **64–69**. These filter coils **64–69** serve to effectively isolate the low frequency oscillator **60** from the high frequency signals of the measurement signal source **70** shown as a one kilocycles per second oscillator. It should be noted that the lead **61** is connected to the excitation coils **35** and **45** of the core assemblies **10** and **11** and that as seen in FIGURE 3 the rods associated with the coils **35** and **45** are in alignment with each other in the complete assembly shown in FIGURE 2. In a similar manner the lead **62** is connected to excitation coils **36** and **46**, and the lead **63** is connected to the excitation coils **37** and **47**. Each of the coils has one end thereof returned to the common signal ground lead **60A** for the oscillator **60**. The geometric and electrical configuration of the system is such that a constant bias field is provided for each of the two core assemblies with the bias fields rotating in the planes of the core assemblies at the angular velocity determined by the frequency of the excitation oscillator **60**.

The measurement signal source **70** shown as a one kilocycle oscillator has its signal output lead **71** connected through the voltage divider **72**, the impedance elements **73** and **74**, and capacitors **75** and **76** to the sensing coils **52** and **52A** (only three of each set of sensing coils being shown in FIGURE 4). One side of the various sensing coils is returned to the common ground **70A** of the oscillator **70** by common leads **85** and **86**. A pair of adjustable capacitors **87** and **88** will be seen to be respectively connected directly across each of the sets of sensing coils **52** and **52A** in the respective core and detector assemblies **11** and **10**. It should be noted that it would also be possible to use the excitation coils themselves as the sensing coils by using suitable frequency separation, such as by using appropriate isolation capacitors.

Since the impedance measuring circuit operates at a very high frequency by comparison to that of the bias field fluctuation, it will be seen that the bias field and the external field can be considered as quasi-static (i.e., varying very slowly with respect to the measurement). The effective field within the two core assemblies **10** and **11** is the result of the superposition of the external horizontal field

Marie Rona to Wed Steven Ross Maris

Miss Marie Helene Rona and Steven Ross Maris will be married in a ceremony at 3 o'clock Saturday afternoon at the University Presbyterian Church in Seattle.

The Rev. Ben Lindstrom of Portland, Ore., will officiate at the rite for the daughter of Dr. and Mrs. Thomas P. Rona, Seattle, and the son of Dr. and Mrs. Robert W. Maris, E1316 Twenty-sixth.

A reception will follow at the home of the bride-elect's parents.

Miss Janet Gwen Maris, sister of the future bridegroom, will be maid of honor.

Patrick Boileau, Portland, Ore., will serve as best man. Ushers will be Michael, Thomas and Chris Rona and Donald and Neil Maris, brothers of the couple.

The couple will reside in Seattle. The bride-elect will be graduated from the University of Washington in June. Maris is attending the U of W Graduate School of Business.

Notes - Killed by "Gerald Wayne Henneke"

1975-07-01-the-seattle-times-pg-f-4-clip-monique-rona-obit

Monique Rona dies; Group Health official

Monique Roberta Rona, 46, of 5770 63rd Ave. N. E., died Sunday about four hours after she was injured in a two-car crash at 26th Avenue Northeast and Northeast 117th Street.

Mrs. Rona was eastbound in Northeast 117th Street about 6:45 p. m. when her car and a car southbound in 26th Avenue Northeast, collided.

The driver of the other car, Gerald Wayne Henneke, 31, of 5823 McKinley Pl. N., suffered nose and leg injuries but was not hospitalized, police said.

Mrs. Rona was head of information processing for Group Health Cooperative of Puget Sound. She was the wife of Dr. Thomas P. Rona.

A native of Paris, she came to Seattle 16 years ago, and for 14 years was deputy director of the University of Washington computer center.

She served on the Presidential Commission on Energy, and was an active member of the Association of Computing Machinery.

Two months ago she was named to the Group Health post.

Services are set for 3 p. m. Thursday at University Presbyterian Church. Home Funeral Chapel is handling arrangements.

In addition to her husband, Mrs. Rona is survived by four children, John, Mary, Thomas, Jr., and John Christopher, and by her mother, Gabrielle Noel, all of Seattle.

The family suggests remembrances to Medic I.

WEAPON SYSTEMS AND INFORMATION WAR

ABSTRACT

Since World War II, advances in technology have brought great increases in the complexity of weapon systems. The need to integrate the many sophisticated subsystems has vastly increased the information flow *within* the weapon system envelope. Overall performance also has come to depend rather critically upon the *external* information flow between the weapon system proper, the target, the command structure, navigation references, and other ancillaries. Because of their susceptibility to countermeasures, these external links and nodes have become major elements of system vulnerability.

Projections related to the information sciences and the associated technology suggest that countermeasures aimed at the external information flow of weapon systems will be further improved to the point that they may well become crucial in influencing the outcome of future engagements.

Functional analysis shows that the information flow to and from a generalized weapon system covers an unusually broad spectrum, ranging from the slowly evolving strategic intelligence all the way to optical communications. Operational information flow, as well as the gathering of intelligence, is susceptible to countermeasures; i.e., disruption and manipulation. The success of countermeasures, as well as that of attacks and counterattacks, hinges essentially on the knowledge of the opponents' order of battle and of the details of the opponents' information structure. Quantitative assessments of the value of countermeasures are possible in a few simple cases.

The potential introduction of advanced and multifaceted countermeasures gives new emphasis to the war-gaming aspects of requirements definition. Considerations of this type may be expected to lead to a modified set of systems requirements such as closing out of strategy options attractive to the enemy, greatly increased number of possible tactical moves for the friendly side, quick change flexibility, and a systematically structured "information war" superimposed on the weapon engagements.

Specific examples from strategic nuclear warfare and from tactical air combat are used as illustrations of the principles involved.

[HC004D][GDrive]

SUMMARY

In the recent decades, many spectacular advances have taken place in military technology. Some of these have improved the performance of individual subsystems such as propulsion, structures, guidance, or warheads; some others have insured the efficient cooperation between all these increasingly complex subsystems by means of integration within the weapon system envelope.

The result of these changes has now been apparent for some time: whenever a weapon can be aimed at its assigned target, the destruction of the latter is assured with a high degree of probability. In the past, protection of targets was often based on passive means such as hardening or on timely counterattacks. There exists now a growing possibility of protecting targets by means of *information denial*. In this protection mode, the defense side aims at depriving the attacker of the essential information required to structure an effective offense. Camouflage, dispersion, and mobility have been used to this effect for many centuries, but modern technology has added strong new impetus to information denial. All forms of warfare, ranging from the highest level nuclear exchange through large-scale "conventional" war to counter-insurgency and guerrilla activity could be impacted.

In many instances, high-performance weapon systems have come to depend critically on interaction with *external* elements, friendly, neutral, or hostile. The command structure, the surveillance and support ancillaries, navigation references, and the target area observables are representative examples. Central to the concept of this *extended weapon system* is the remoteness of the phy ical elements. Communication links are thus introduced that require a new level of integration; more importantly, they introduce new opportunities for the enemy to practice modern and quite effective versions of information denial. Disruption and manipulation of the adversary's information flow by means of countermeasures have rapidly become some of the most potent means to secure military advantage.

There are numerous confluent technologies at hand to reinforce the belief that information-related countermeasures will further grow in efficacy and sophistication; many new areas of application can be readily envisioned. The basic technology aspects have to do with the theoretical and practical advances in the use of the full electromagnetic spectrum ranging from ELF* to gamma rays and of the acoustic spectrum from seismic and tidal pressure fluctuations to ultrasounds at thousands of megahertz in frequency. Transducers are available to transform just about any physical phenomenon into electrical signals, with the attendant capability for transmission, processing, and display for use by human operators. Equipment and software for rather sophisticated information processing, at rates compatible with the speed and frequency domains of interest to weapon systems, are now available within cost, power, weight, and reliability constraints required to satisfy the demands of the most advanced forms of countermeasures.

In the simplest form, information-flow-related countermeasures attempt to disrupt the communication and information links of the enemy in the last few moments immediately preceding the detonation of a weapon. Jamming of the command link of a surface-to-air missile is a typical example. It is, however, readily apparent that countermeasures of this type can be applied at many points of a weapon system, covering in fact the whole period of its evolution from development through deployment, mission, and post-mission phases. The spectrum of events pertinent to the information flow, which is the potential target of countermeasures, covers an extremely broad frequency domain: slowly varying strategic intelligence is updated in bursts occurring in a matter of months or years; tactical intelligence, surveillance, or reconnaissance may deal with event durations measured in days or hours; and events related to the terminal engagement can take place in seconds or even microseconds. Countermeasures may address any or all of these frequency domains; they may be concentrated in any one locale, or again dispersed over many elements of the

* See Glossary, page 71

[HC004E][GDrive]

External Information Flow

Up to the present, we have examined the information flow within the weapon system envelope. We must now go one step further. Referring to Figure 9, the weapon system (A), including the platform, is now shown in the center. The relation of the weapon system to other elements contributing to its operation has been made explicit. On the friendly side, the weapon system must interact with its own command structure (C), with the ancillary and support systems (F), and with the friendly, neutral, or natural navigation reference systems (D). Both weapon and platform have to cope with the natural or hostile man-made environment (E). Finally, the weapon must interact with the target (B) prior to the instant of contact.

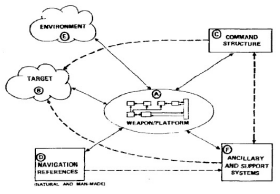

Figure 9. Extended Weapon System and External Information Flow

It is convenient to call all the information-related components within the weapon system (A) the *internal information system* and to consider that all the other elements such as (B), (C), (D), (E), and (F) are tied together by what could be called the *external information system*. All the elements and all the links are, or conceptually could be, present in all weapon systems, even though some of them are less important or evident than some others. Elements other than the weapon system; i.e., boxes (C), (D) and (F), may have *internal* information systems of the same order of complexity and cost as the weapon system (A).

A few examples will allow us to gain more concrete understanding of what these external information links really contribute. The link (A)-(B) between the weapon and the target may convey terminal guidance, or, if properly decoyed, false terminal guidance. If the target is surrounded by active defense, that same link may also serve to convey false observables (decoying) to the defense. Link (A)-(C) between the weapon and the command structure would typically transmit target designation, status report, launch command/confirmation type information. Link (A)-(D) between the weapon and navigation references may sense position of stars, satellites, terrain elements, or artificial land beacons. Link (A)-(F) between the ancillary/support systems and the weapon would typically provide surveillance and reconnaissance information, target identification, warning, intercept control, and vectoring or IFF.

An escort airplane intended to protect a bomber can be considered as an ancillary; all information related to such aerial engagements would flow through link (A)-(F).

The link (A)-(E) between the weapon and the environment allows the weapon to sense its own environment and adapt its surveillance or guidance sensors to the prevailing conditions.

The foregoing is reasonably well understood and may be analyzed within the purview of the weapon system itself. The situation becomes more complicated when we consider links and interactions between the external elements. For instance, a relationship exists between link (D)-(F) and link (B)-(F). The location of the target must be defined with respect to the navigation references. Similarly, link (B)-(C) should be present, either directly or via ancillaries

HC004F][GDrive]

(C)-(F)-(B). If the latter is too slow, the commander may want to have direct access to the target. This would be the case, for instance, when the Command Information Center of a combatant ship directs the air battle between fighter/interceptors and the enemy strike forces.

The link (C) (F) exists mostly to convey the status, availability, and confirmation-type data in relation to the ancillary and support systems.

As an illustration, in Figure 10 the role of ancillaries in a "smart missile" is represented. The missile is capable of illuminating the target and sensing target observables, provided that a pre-mission intelligence element has supplied *in advance* the criteria for signature classification and that a pre-mission surveillance/reconnaissance element has supplied rough target location.

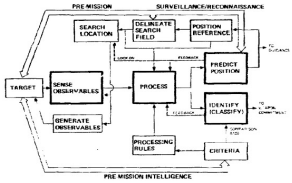

Figure 10. Missile Acquisition and Tracking Functional Relationships — Ancillaries

These examples have been described at some length to support the argument that successful operation of the weapon system is just as critically dependent on the operation of all pertinent elements portrayed in Figure 9 as on the intrinsic capability of the weapon system itself. To put it another way, no matter how complex, competent, or costly the weapon system and its platform might be, if the surrounding external elements fail to perform their tasks, the mission objectives will not be achieved.*

The situation is even more complex owing to the possible interaction of external links with each other. For instance, if guidance or navigation signals are emanating from the weapon system (and this may be highly desirable from the accuracy viewpoint), they may reveal the platform position at the same time and thereby open the way to enemy counterattack.

Complexity is not the only reason why the "extended" weapon system, including all the external elements, is not considered in general as an integrated supersystem. Institutional barriers also exist. The various elements shown in Figure 9 are not necessarily under the cognizance of the same agency; sometimes they involve several sovereign countries. Developments are not necessarily simultaneous; budget considerations quite often cause relatively modern weapon systems to interface with obsolete ancillaries and vice versa. For whatever reasons, integrated system requirements at the extended weapon system level are hardly ever formulated. Examples of this type of difficulty can be found in the areas of "warning on critical events" as related to ICBM launch command, or in the operation of hard-site ABM defense as related to the ICBM launch environment.

The common characteristic of external information systems is that it requires sensing or communications at a distance between physically remote elements. These all involve electromagnetic or acoustic propagation and are, therefore, potentially accessible to hostile interference.

* For instance, in World War II, even though the Germans had what at that time was considered to be a highly competent strategic bomber force, the successful interference with their land-based long-range navigation beams resulted in quite unacceptable targeting errors.

What is "information warfare"? Is it nothing more than a bumper sticker, used as a "quick fix" rescue for budgets and programs that find it useful to attach themselves to the hot new concept? Is it such a revolutionary new amalgam of technologies and concepts that old and traditional forms of warfare are soon slated to fall into the same receptacle in which outmoded military technologies such as the catapult and war galley slumber? Is warfare as we understand it, featuring "blast, heat, and fragmentation," about to become obsolete? ***[Author's note : "I am indebted to Lieutenant General Mike Hayden, Director of the National Security Agency-the DIRNSA-for this very descriptive phrase. "]*** *The intent of this brief introduction to information warfare (IW) and information operations (10) is to both explore these issues and present the thesis that they are best understood in light of the environment in which they take place-the information environment-and to explore the relationship of that environment to the specific topic on which this book is focused, computer network attack.*

What is Information Warfare?

A useful starting place is to trace the evolution of the term information warfare itself. ***The earliest use of the term in the United States probably originated in the Office of Net Assessment, where in the 1970s Dr. Tom Rona was investigating the relationships among control systems, a field known as cybernetics.*** *Dr. Rona described the competition between competing control systems as "information warfare," in the sense that control systems can be described as the means for gathering, processing, and disseminating information, processes which can be diagrammed and described with flow and feedback charts of mind-numbing dryness and complexity. [This author first met Dr. Rona and heard his concepts during a presentation on June 13, 1994, at the Information Resources Management College, National Defense University, in Washington DC. He defined IW as "the sequence if actions undertaken by all sides in a conflict to destroy, degrade, and exploit the it!fonnation systems if their adversaries. Conversely, information warfare also comprises all the actions aimed at protecting infonnation systems agaillSt hostile attempts at destruction, degradation and exploitation. ""Information Warfare Action" take place in all phases if conflict evolution: peace, crisis, escalation, war, de-escalation and post conflict periods." Dr. Rona, a gentle man and brilliant analyst, unfortunately passed away in December 1997. For an example ofhis work, see Weapon Systems and Information War, a study prepared for Boeing in 1976.] In 1993 the Department of Defense published an official definition for the term, in a highly classified DoD Directive, TS3600.1. There were actually several definitions, at differing levels of classification.3 Not surprisingly, this definition was frequently revised as the operational and organizational implications of the concept evolved. The current definition has the record for longevity-more than five years at the time of this writing, since the promulgation of the current guidance on information warfare and information operations in DoD Directive 3600.1 on December 9, 1996.4 The publication of Joint Publication 3-13,Joint Doctrine for Information Operations, in October 1998 probably ensures that the current official DoD definitions ofIW and 10 will remain in effect for some time longer.s*

The present definitions leave much to be desired, however, if one is hoping to find explanations that clarify and explore what might constitute the character, conduct, and intent ofIW and 10. But since one must understand what 10 is in order to move to its less comprehensive building block, IW, these definitions do provide a useful starting point: Infonnation Operations: Actions taken to affect adversary infonnation and infonnation systems while defending one's own infonnation and infonnation systems. Infonnation Warfare: Infonnation operations conducted during time of crisis or conflict to achieve or promote specific objectives over a specific adversary or adversaries.

1974(ish) to 1980 - "Ben Plymale, a vice president at Boeing and former defense official from the Nixon administration, was Thomas Rona's friend and mentor"

20. ABSTRACT (Continue on reverse side if necessary and identify by block number): This report distinguishes between international political stability and strategic nuclear stability, providing a concise history of each concept. It then defines the following subcategories of strategic nuclear stability: deterrence stability, crisis stability, arms race stability, and escalation stability. The development of what is termed orthodox nuclear strategic doctrine, which holds that stability depends upon both nuclear superpowers' having invulnerable retaliatory forces and vulnerable societies

The question of Soviet cooperation leads to a second weakness of the strategic nuclear stability concept. Although some pro-stability analysts recognize that carrying out a stability policy would be difficult without a US-USSR consensus (Kahan 1975:270), there is a tendency among others to believe that stability will work automatically if the United States follows the rules. The ACISs devote very little attention to what the Soviet Union has done about weapons development and deployment, and a good deal of attention to what "a conservative Soviet planner" might fear from US weapon innovations. (For example, US Congress 1979:17.) There is a widespread failure to realize that if the Soviets develop or deploy new weapons, or add significant protection for their populations, as they are doi , then stability, even as defined in orthodox fashion, will no longer exist. The United States has to be ready with responses that can restore stability very quickly. (Rona 1977:5) Changes in stability as a result of altered deployments are shown in schematic form in Figure 2, p. 80 , above.

With all its weaknesses, however, the stability concept does provide some kind of guidelines for a coherent strategic nuclear policy. It offers a standard by which weapons can be judged, and choices made, even though, as has been shown above, the same weapon may be found to be stabilizing in several ways and destabilizing in several others. The stability-based approach may have much to recommend it over a system without

92

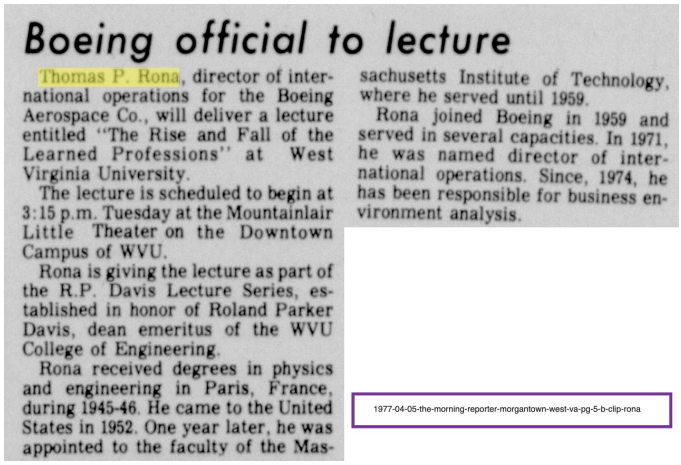
1977 (April 05) - Delivering lecture in West Virginia;

Full pages : [HN01AX][GDrive] / [HN01AZ][GDrive]



Boeing official to lecture

Thomas P. Rona, director of international operations for the Boeing Aerospace Co., will deliver a lecture entitled "The Rise and Fall of the Learned Professions" at West Virginia University.

The lecture is scheduled to begin at 3:15 p.m. Tuesday at the Mountainlair Little Theater on the Downtown Campus of WVU.

Rona is giving the lecture as part of the R.P. Davis Lecture Series, established in honor of Roland Parker Davis, dean emeritus of the WVU College of Engineering.

Rona received degrees in physics and engineering in Paris, France, during 1945-46. He came to the United States in 1952. One year later, he was appointed to the faculty of the Massachusetts Institute of Technology, where he served until 1959.

Rona joined Boeing in 1959 and served in several capacities. In 1971, he was named director of international operations. Since, 1974, he has been responsible for business environment analysis.

Aerospace engineer is lecturer

Threats to the traditionally "learned professions" could have a dramatic and irreversible impact upon society, to an engineer who will lecture on the campus of West Virginia University at 3:15 p.m. Tuesday in the Mountainlair Little Theater.

Thomas P. Rona, director of international operations for the Boeing Aerospace Co., will present the ninth annual R. P. Davis memorial lecture on the practice of engineering. The lecture series is sponsored by the College of Engineering in memory of Dean Emeritus Roland P. Davis.

In his remarks Tuesday, which are open to the public, Rona will discuss the "considerable social privileges" granted to the "learned professions" of priests, doctors, lawyers, scientists and engineers, in return for "satisfying the perceived needs of society."

Presently, threats to that status may force a realignment of the efforts of these professionals, Rona will explain, as his remarks discuss the most serious concerns associated with this social phenomenon.

1978 - 1984 (dates approximate) - Thomas Rona works for 4 years with Andrew W. Marshall of the Office of Net Assessment project, while still officially with Boeing - Marshall "supported Rona's work on the theory and practice of information war"

See Andrew Walter Marshall (born 1921)

1. Chapter 4 (of The New Face of War: How War Will Be Fought in the 21st Century Paperback – October 26, 2007 by Bruce D Berkowitz) - [HB0052] [GDrive]
    1. *"[**Andrew Walter Marshall (born 1921)**] began in 1978 to draft a **Net Assessment on Command and Control**. "The more we looked at it, the more we could see that the center of the change in warfare was in the sensors and the information systems. The information aspect of weapons had always been important, but now it was more important than ever. So one of your key operational goals had to be to establish an advantage," Marshall recalls.*
    2. ***Before long [Andrew] Marshall heard about [Thomas] Rona's monographs on "information war" at Boeing. The two met and hit it off. Marshall could see Rona was onto something.** "No doubt about it. Tom was the first person to put it all together," recalls Marshall. **For the next four years Marshall supported Rona's work on the theory and practice of information war, or, as it came to be called, information warfare.** It was a bargain, as Boeing still picked up half of Rona's salary. [NOTES - Tom Rona left Boeing on March 1984 ...]*
    3. ***As one connection led to another, Rona himself came to Washington a few years later. [Ben Telfer Plymale (born 1926)], a vice president at Boeing and former defense official from the Nixon administration, was Rona's friend and mentor. Plymale introduced Rona to [William Robert Van Cleave (born 1935)], a professor at the University of Southern California. Van Cleve had been an adviser to Ronald Reagan during the 1980 campaign and was directing the Defense Department transition team for the new administration. Rona started working for van Cleve, and soon caught the eye of [William Robert Graham (born 1937)], who was also working on the transition and was about to become Reagan's new director of the White House Office of Science and Technology Policy. Graham offered Rona a job as deputy director.***

1983 (Oct) report - Credit given to Thomas Rona in "BALLISTIC MISSILE DEFENSES AND U.S. NATIONAL SECURITY SUMMARY REPORT"

PDF (original) : [HG0081][GDrive] / PDF (with OCR) - [HG0082][GDrive]

Fred S. Hoffman, Study Director / October 1983

Preface:

President Reagan has directed an "effort to define a long-term research and development program ... to achieve our ultimate goal of eliminating the threat posed by strategic nuclear missiles .... " The President noted that the achievement of the ultimate goal was a "formidable technical task" that would probably take decades, and that "as we proceed we must remain constant in preserving the nuclear deterrent...maintaining a solid capability for flexible response ... pursue real reductions in nuclear arms ... (and) reduce the risk of a conventional military conflict escalating to nuclear war by improving our nonnuclear capabilities."

Two studies assisted in that effort: {I) the Defensive Technologies Study (DTS) to review the technologies relevant to defenses against ballistic missiles and recommend a specific set of long-term programs to make the.necessary technological advances, and (2) the Future Security Strategy Study (FSSS) to assess the role of defensive systems in our future security strategy.

The implications for defense policy, strategy, and arms control were addressed by two FSSS teams: an interagency team led by Mr. Franklin C. Miller~ and a team of outside experts led by Mr. Fred S. Hoffman. This is a report on the results of the work of the team of outside experts. The work was done under the auspices of the Institute for Defense Analyses at the request of the Office of the Under Secretary of Defense for Policy to assist the interagency team.

This report and its conclusions do not necessarily represent the views of the Department of Defense or the Institute for Defense· A,nalyses.

1986 - 1988 : CILTS (Commission on Integrated Long-Term Strategy) : The CILTS Working Group on the Future Security Environment

PDF of book "SIX DECADES OF GUIDED MUNITIONS AND BATTLE NETWORKS: PROGRESS AND PROSPECTS" by Barry D. Watts : [HB004Z][GDrive]

lems are solved. Rather they merely reveal how much care is needed in discussing them.

Questions about Future War and an Anomaly

As mentioned at the end of Chapter I, the overall aim of this chapter has been to address the question: How ought one think about the emergence of guided weapons? By the mid-1980s both Soviet military theorists and Western observers were actively trying to think through how guided munitions and battle networks might eventually affect the conduct of war by military forces able to exploit them. This final section of Chapter II reviews the main questions about guided munitions raised in the late 1980s by Andrew Marshall and Charles Wolf during their deliberations on the future security environment as co-chairmen of a working group for the Commission on Integrated Long-Term Strategy (CILTS). Additionally, the discussion also highlights one anomaly regarding reconnaissance-strike systems that has become increasingly apparent during the last decade.

The Commission on Integrated Long-Term Strategy was begun in the fall of 1986 at the direction of President Ronald Reagan's defense secretary, Caspar Weinberger, and his assistant for national security affairs, John Poindexter. The commission's initial mandate was to propose "adjustments to U.S. military strategy in view of a changing security environment in the decades ahead."[152] Co-chaired by Fred C. Iklé (then undersecretary of defense for policy) and Albert Wohlstetter, CILTS had eleven other commissioners, including Zbigniew Brzezinski, Henry Kissinger, former NATO supreme commander General Andrew Goodpaster, Samuel Huntington and former JCS chairman General John Vessey.[153]

[152] Iklé and Wohlstetter, *Discriminate Deterrence: Report of the Commission on Integrated Long-Term Strategy*, p. i. By the time this report was published in January 1988, Frank Carlucci had replaced Weinberger as defense secretary and Colin Powell had become the assistant for national security affairs, having replaced Carlucci who had held the job from December 2, 1986, until November 23, 1987.

[153] The other CILTS members were Anne L. Armstrong, William P. Clark, W. Graham Claytor, Jr., Admiral (USN, retired) James L. Holloway III, Joshua Lederberg, and General (USAF, retired) Bernard A. Schriever.

[HB0050][GDrive]

The CILTS effort was supported by a number of working groups, whose studies were not published until after the commission's overall report, *Discriminate Deterrence*, appeared in January 1988.[154] *Discriminate Deterrence* did mention the possibility of an emerging RMA driven by the exploitation of microelectronics, information processing, and other technologies. In fact, it observed that the Soviet military was already "engaged in a major effort to understand the implications" of being able to employ precision munitions across wider geographical areas with greater rapidity and intensity than had been previously possible.[155]

However, detailed examination of these prospects and possibilities did not emerge until the report of Marshall and Wolf's CILTS working group on the future security environment was published in October 1988.[156] This group took seriously the possibility that Soviet military theorists might be right in anticipating that the conduct of war was entering a period of major or discontinuous change:

> The Working Group believes that the Soviets are correct in their assessment that the advent of new technologies will revolutionize war, and not merely make current forces marginally better at what they do. In the same way that long-range rifles and railroads transformed combat in the mid-19th century (and tanks and aircraft did in the mid-20th century), the new technologies will profoundly alter tactical requirements, operational possibilities, and even, in some cases, strategic choice in the early 21st century. New theaters of strategic concern—space, most notably—will open up, and previously discarded options (ballistic missile defense, for

[154] The topics assigned to the working groups were "the security environment for the next twenty years, the role of advanced technology in military systems, interactions between offensive and defensive systems on the periphery of the Soviet Union, and the U.S. posture in regional conflicts around the world" (Iklé and Wohlstetter, *Discriminate Deterrence*, p. i).

[155] Iklé and Wohlstetter, *Discriminate Deterrence*, p. 8.

[156] Members of the CILTS working group on the future security environment included Eliot A. Cohen, David F. Epstein, Fritz Ermarth, Lawrence Gershwin, James G. Roche, Thomas Rona, Stephen P. Rosen, Notra Trulock, III, and Dov Zakheim.

COMMISSION ON INTEGRATED LONG-TERM STRATEGY

MEMORANDUM FOR THE COMMISSION ON INTEGRATED LONG-TERM STRATEGY

Co-Chairmen
Dr. Fred C. Ikle'
Professor Albert J. Wohlstetter

Members
Ambassador Anne Armstrong
Dr. Zbigniew Brzezinski
Judge William P. Clark
Mr. W. Graham Claytor, Jr.
General Andrew J. Goodpaster (USA, Ret.)
Admiral James L. Holloway, III (USN, Ret.)
Professor Samuel P. Huntington
Dr. Henry A. Kissinger
Dr. Joshua Lederberg
General Bernard A. Schriever (USAF, Ret.)
General John W. Vessey (USA, Ret.)

The Working Group on the Future Security Environment is pleased to present our report to the Commission on Integrated Long-Term Strategy.

This report is in general consonance with the Commission's report, *Discriminate Deterrence*, which made substantial use of our preliminary findings and conclusions. The Working Group report provides more comprehensive and detailed information in support of the Commission's report. However, the report is the responsibility of its authors and the Commission does not necessarily subscribe to all of its details.

Because a separate working group addressed issues of "low-intensity conflict," this report gives limited attention to smaller regional wars, insurrection, and terrorism.

The members of the working group include Eliot A. Cohen, David F. Epstein, Fritz Ermarth, Lawrence Gershwin, James McCrery, Jeffrey Milstein, James Roche, Thomas Rona, Stephen P. Rosen, Dennis Ross, Notra Trulock, Dov Zakheim, and Barbara Bicksler (rapporteur).

STATEMENT FOR COMPLETION BY PRESIDENTIAL NOMINEES

(If more space is needed, please use attached REMARKS sheet)

A. BIOGRAPHICAL DATA

1. Name: RONA (Last) THOMAS (First) PAUL (Other)

Address: 5902 Mt. Eagle Drive (Current residence)
Alexandria, VA 22303

Executive Office of the President
Office of Science and Technology Policy
Room 5013, NEOB, 17th&Penn Ave, NW
Washington, D. C. 20506

2. Position to which nominated: Associate Director, OSTP
Date of nomination: June 1987

3. Date of birth: January 17, 1923 (month) (day) (year)
Place of birth: Budapest, Hungary

4. Marital status: Married
Full name of Spouse: Jinnett McBride Rona

5. Names and ages of children: John Christopher Rona (29)
John Michael Rona (35)
Thomas Paul Rona, Jr. (33)
Marie Helen Rona (34)

6. Education:

Institution	Dates attended	Degrees received	Dates of degrees
Ecole d'Electrictie and Mechanique Industrielle (A.K.a. "Ecole Violet")	June 1939 Sept 1940	Brevet Industriel (HS Equivalent)	Sept 1940
Ecole d'Electrictie and Mechanique Industrielle	Sept 1940 June 1943	BS in ME	June 1943
Ecole Superieure d'Electrictie	Sept 1943 June 1945	EE (Graduate (Degree)	June 1945
University of Paris (Sorbonne)	June 1945 June 1946	Certificate of Lic. in Physics (Electronics)	June 1946
Massachusetts Institute of Technology	June 1952 June 1955	Sc.D. in E.E. with Minor in Industrial Management	June 1955

[HG007K][GDrive]

7. Employment record:

From	To	Name of Employer	Address	Type of Work
4/3/84	Present*	Department of Defense (OSD)	The Pentagon, Washington,DC	Policy Development
7/20/59	3/84	The Boeing Company	Seattle, WA	Requirements Analysis
9/52	7/19/59	Massachusetts Institute of Technology	Cambridge, MA	Teaching and Research
9/51	9/52	University of Montreal (Ecole Polytechnique)	Montreal, PQ	Teaching
8/51	9/51	Unemployed		
9/49	8/51	Self-Employed	Paris, France	Lumber Business
8/47	9/49	Self-Employed	Duala, Cameroun	Consulting
7/46	8/47	Office National d'Etudes et Recherches Aero-nautiques	Paris, France	Research
6/43	6/46	Thompson Houston Company	Paris, France	Research

* Since 12/86 Detailed to the Office of Science and Technology Policy as Assistant Director for Government Programs

Consulting: Edgerton, Germeshausen and Grier, Boston 1955-1959
USAF (Holloman Air Force Base) 1956-1959
Babcock and Wilcox Company, Lynchburg, VA 1958-1979

8. Government experience.

June 1956 through July 1959	Consultant to U.S. Air Force, Holloman AFB
June 1982 through April 1984	Army Science Board - Member
March through April 1984	Consultant, DOD/OSD(P)
April 1984 to date	DOD/OSD(P) Deputy Director for Space and Intelligence Policy (through May 1985) then Special Assistant for C^3I/Space Policy
Since December 1986	Detailed to OSTP as Assistant Director for Government Programs

9. Political affiliations activities: List all memberships and offices held in or financial contributions and services rendered to all political parties or election committees during the last 10 years.

From 1979 through 1983 State Republican Party, Washington
Aggregate political contributions not exceeding $300 over these years.

Term "information dominance"

1990-06_Command_Control_Common_Defense

1990 (October 08) - Interview in "Defense News"

Page 1 (cover) : [HP003V][GDrive]

Notes : At this time, Thomas Rona is working for https://en.wikipedia.org/wiki/ICF_International .

ONE ON ONE

Thomas Rona

C³I Consultant

The role of information in wartime has been one of Thomas Rona's main interests for about 30 years.

Rona, who graduated in 1946 from the Sorbonne in Paris, moved to the United States and worked for Boeing Aerospace from 1959 until 1984 when he became deputy director for space and intelligence policy in the Department of Defense. In December 1986, Rona joined the White House staff as deputy director of the Office of Science and Technology Policy.

Since November 1989, he has devoted his time to private consulting. Rona continues to research how military services struggle over the collection, use and protection of information in peacetime and in combat, which he calls the "information war." The information war is becoming more critical, argues Rona, because the side that handles information skillfully will have a decisive advantage, despite the possibility of confronting superior weapons and equipment.

Defense News *staff writer Neil Munro interviewed Rona in his office at ICF Corp., Fairfax, Va.*

PHOTO BY DARREL ELLIS

Q. What is the role of information and intelligence in warfare?

A. Information has always been an important factor in war. But because of modern [highly accurate] weaponry, information becomes not only critical, but technically complex. Modern weapons need and use an enormous quantity of prompt, accurate information. If they do not have it, they cannot operate.

We obviously provide that information to cause our weapons and operations to succeed. But by doing so, we expose our massive communications and information structure to enemy counteraction. This manifests itself in interference [with] communications, exploitation which works by finding out what they are doing by listening. Also, we need to protect our own structure against similar action by the enemy.

This is a complex series of actions which are superimposed at all times on the movement of weapons, vehicles and people. It is there all the time, starting from the concept of a weapon system to delivery of that weapon to the target. It even goes beyond, because you need to assess if you have killed the target. For example, [the enemy] showing a bunch of dead tanks might convince you everything is OK.

Q. How will information war be applied in combat?

A. In modern warfare, both sides will go completely out of their way to confuse [each other's] decisions. If 500 missiles are flying in our direction, then we have no problem because it is either too late to do anything, or we have the preparations to counter them.

But the enemy is not going to do that. The enemy is going to send you a message, perhaps an overt message, saying I don't intend to attack you. We can take the invasion of Kuwait as an example of that. Saddam Hussein was negotiating down to the eve of the invasion, and the president of Egypt came back from Baghdad saying Iraq had no intention to attack.

So the idea of hiding your intent, of sending out confusing signals, disturbing [the enemy's] decision-making, are very important, especially when you are using highly powerful weapons. It is extremely important, and we do not yet know how to handle it.

Q. How should the Department of Defense respond to the increased importance of information war?

A. The logical conclusion ... is to make sure you provide flexible tactical options, and diversify to ensure there are many solutions [to every military problem]. Also, [tactics should be] time variable, and as you plan your operations you must make sure you include moves related to the information war. This obviously puts a different perspective on requirements, especially for command and control. ... It places additional requirements on command and control systems in as much as they need to be improved with respect to [information] security, discrimination, and adaptiveness. The DoD is increasingly applying these views.

Q. How does this affect design of weapons?

A. Information war must impact weapon system requirements. It also offers a number of new moves at the tactical level. In the good old days, when the information war was not accepted at [the tactical] level all you could do was shoot or not shoot, move or not move. That was tactics, [but] today you can add deceptive moves and destruction of the enemy's command and control structure.

Therefore the [pre-war] analyses of engagements must take into account the information war, as well as those in the conventional physical war.

Q. How well have the services incorporated in weapons, tactics and doctrines, the role of information in combat?

A. The military people understand how important it is. The whole idea of command and control is a military concept ... but there is still a lot of progress to be made integrating it into doctrine and weapon development.

Q. Is the concept of information warfare being built into weapons?

A. Somewhere until the mid 1960s, whenever a weapon system was developed, the information warfare aspect was incorporated only afterward. The progress in understanding can be measured by the fact that some of the weapon systems are based on the concept of information denial. The stealthy B-2, is one example. Also, the AWACS [Airborne Warning and Control System aircraft] is entirely constructed to gather the right information, process it and convey it to the right people. You can see what it does in the Persian Gulf; it controls the situation to our advantage.

Another example is the Strategic Defense Initiative. It is a very complex task, and it turns out information is the key. How do you acquire it? How do you control it? How do you make decisions in a timely manner? How do make sure the enemy has no hope of destroying our own information structure?

Q. The technology is moving forward, but are the services using this technology in the right way?

A. The B-2 airplane, for example, is expensive, and so it is a matter to decide whether to expose such an expensive piece of equipment to a first-class air defense. You may choose to attack the target in other ways. But the mere fact that you have [the B-2] forces the enemy to install extremely expensive defenses, so that the battle really starts well before the military operation.

It starts at the development phase. You develop the stealth bomber. In order to counter that, the putative enemy must develop an extremely expensive sensor and air defense system, which costs a pretty penny. And then of course, you may also choose to use missiles instead.

On the larger point, I would not gainsay the judgment of seasoned military officers. Now I will not say that all military development decisions are logical and correct, or in the long run prove valuable. But on the whole, we came out ahead of any opposing empire and ... yet it was expensive, but not that expensive compared to the price of a war. You show me one agency, or one organization in a modern society, that does not make mistakes.

Q. Does it take time for organizations to change themselves to respond to the increased importance of information in wartime?

A. It is difficult to measure how well the concept has penetrated the thinking, and the subliminal thoughts of the servicemen. But in all three services, and at the Department of Defense level, when they talk about command and control, the long distance interaction among systems and people, it becomes very well understood that communication is not the only thing that matters.

The thinking of the top commander [should be] infused with the concept of information war — and that is making enormous progress.

Q. What is the role of time in information warfare?

A. For example, with smart weapons ... once you have found [a target], they will try to prevent you from geting to it. This is where the tempo of operations really begins to play. You have once in a while a smart defensive move like jamming. If jamming is there forever, you will detect it and counter-countermeasure it. But if the jammer jumps from frequency to frequency, that is, it is time variable, [your task becomes harder].

Then you have two choices. Either you make it [the smart weapon] so brilliant that it detects the defense environment and concocts its own penetration tactics without your interfering.

Or you have a command link [sending information to the missile]. You watch the engagement from far away and you detect what the enemy is doing. Then you inject that intelligence to the brain of the missile. However, neither of these yet exist.

Q. Where do we go from here?

A. The technology is moving so fast ... that little [computerized] boxes can handle all the information [we need]. We are at the foothills of this concept and 10 years from now it will be obvious.

Thomas P. Rona, 74, a lecturer and consultant who was a former deputy director of the White House Office of Science and Technology, died of hypertensive cardiovascular disease Dec. 27 at his home in Bethesda.

Dr. Rona came to Washington at the beginning of the Reagan administration. He held several posts dealing with science policy before becoming office deputy director in 1986. He retired in 1989 and since then had been a lecturer and consultant.

His clients included the Defense Department, the Mitre Corp., the Bionetics Corp. and the Johns Hopkins University's Applied Physics Laboratory. He was the author of the 1982 book "Our Changing Geopolitical Premises" and was writing a political novel at the time of his death.

Dr. Rona, who was born in Hungary, was an electrical engineering graduate of the Ecole Polytechnique in Paris. **He moved to Montreal in 1949** and then to Boston, where he served on the faculty of the Massachusetts Institute of Technology. He received a doctorate in engineering from MIT. In 1959, he joined the Boeing Co. in Seattle. He lived in Seattle until moving to the Washington area. His hobbies included painting, listening to classical music and raising tropical fish. He spoke four languages and held several technical patents.

His first wife, the former **Monique R. Noel**, died in 1975.

Survivors include **his wife, the former Jinnett McBride, whom he married in 1987 and who lives in Fairfax**; four children from his first marriage, John Michael Rona, Thomas Rona Jr. and Maree Helen Rona, all of Seattle, and **John Christopher Rona of Mount Vernon, Wash.**; a brother, **George, of Brussels**; and seven grandchildren.

[HB004X][GDrive]

Chapter 3 “THEY ARE ALREADY AMONG US” T o understand modern warfare, you need to begin, of all places, in Budapest.

[...] Much of the twentieth century’s brainpower was born within Hungary: John von Neumann, inventor of both quantum mechanics and the computer program; atomic scientists Edward Teller, Eugene Wigner, Leo Szilard, and Isidor Rabi; Elie Wiesel, humanitarian and recipient of the Nobel Peace Prize; Andy Grove, one of the founders of Intel Corporation. All were Hungarians. Or, more precisely, ex Hungarians. Budapest may resemble a fairyland. Its onion-domed churches and hot-spring fountains may seem enchanting. But the city has always had a dark side. Hungary is at the crossroads of Europe, another way of saying that it has been on the invasion routes connecting Germany, Russia, and Turkey.

Things got especially chaotic in Hungary after World War I, when the Allies carved up the Austro-Hungarian Empire, and got even worse after the Fascists and Communists began to compete for control. Eventually the Fascists won out, and Hungary sided with Nazi Germany during World War II. As a result, the U.S. Fifteenth Air Force flattened Budapest, and the Red Army pillaged what remained. The combination of a cosmopolitan society, a devotion to education, and a penchant for war and riot has made Hungary a leading exporter of human genius.

Among those fleeing all the chaos were Edward and Irene Rona, **who sent their son Thomas and his older brother George to the more tranquil environs of Paris soon after Tom was born in 1923. Tom grew up a Parisian, taking his finals in engineering at the École Polytech-nique on V-E Day. After a brief detour with the French engineering corps building bridges in Cameroon (partly to dodge an irate father and a shotgun marriage), Rona returned to Paris and met Monique Noel, a bank clerk. Tom and Monique soon married.**

Tom and Monique began moving farther and farther west to escape the chaos and constraints of the Old World—first to Montreal, then to a junior faculty position for Tom at the Massachusetts Institute of Technology. By that time he and Monique had three sons and a daughter. **An assistant professor at MIT earned an annual salary of $2,400, so money was tight. Tom heard about an opening for a staff scientist at Boeing. He and Monique flipped a coin. Boeing won, and they piled the four kids in the car and began the drive to Seattle. Tom reported to work, and Monique got a job at the University of Washington.**

It’s hard to tell if Rona ever actually used his engineering degree at Boeing, at least in the sense that he never designed a bomber or missile. Officially he was a senior scientist. Defense contractors like Boeing charge the government an extra fee beyond the basic materials and labor it takes to build a B-52 or an air-launched cruise missile. This money goes into an account for preparing bids and proposals (B&P, in defense contractor jargon), which Boeing used to pay for most of Rona’s salary.

The idea was that Rona would develop new ideas for using military hardware—hopefully, new Boeing hardware. In any case, Rona effectively had a license to look at any technology or topic that seemed interesting and was a potential market for Boeing. It was almost as good as being a professor at a major university, if not better.

People were still trying to assimilate the lessons of World War II when Rona arrived at Boeing. The war was just ten years past, and everyone was still trying to figure out the legacy of what Winston Churchill called the “wizard war”—the contest of electronic weapons and countermeasures.

The British had learned the hard way just how complex this game could be. **Electronic warfare had become a critical factor in World War II during the Battle of Britain.** In 1940 émigrés who had escaped the Continent told British intelligence that the Germans had developed some kind of “beam” weapon. At first the Brits thought this might be a ray gun that could shoot down aircraft by electronically frying their ignition systems; the refugees had talked about the Germans’ testing a “beam weapon that stopped cars.”

When they dug deeper into the reports, though, the Brits discovered that translators had mangled the syntax; what the émigrés really meant was that the Germans were testing a weapon that required them to stop cars-that is, stop nearby traffic to avoid radio interference. Later the British bugged the cells of some German POWs and learned that the weapon was a radio device for guiding bombers to their targets. 1

The Luftwaffe had developed a system of steerable radio beams criss-crossing Britain from stations in France and Germany. A primary beam traced a path to the target for the pilot to follow. If the pilot went off course, the beam would grow weaker, and this would trigger a buzz in his headset telling him to correct his heading. Additional beams bisected the flight path to alert the bombardier as he approached the release point. When the signal from the final crossbeam

his heading. Additional beams bisected the flight path to alert the bombardier as he approached the release point. When the signal from the final crossbeam peaked, the bombardier heard a signal in his earphone and he knew he was over the target. It was like an electronic ". marks the spot."

Eventually the British learned how to deduce the direction of the beams and thus figure out which targets to protect. Yet this breakthrough had little to do with detecting the beams themselves. The real trick was in intercepting and deciphering the communications that the Luftwaffe used to tell their radio stations where to aim their beam each night. This revealed the direction and frequency of the beams, and with this information, the British could both determine the target the Germans planned to bomb, and also track a beam back to its transmitter.

The British soon learned how to transmit their own signals on the same frequency, jamming the receivers on the aircraft or causing the bombardier's signal to go off before his aircraft actually reached its target. Combined, all of these separate ingredients provided the components of an information warfare operation. The British learned where the Germans planned to attack, manipulated the Germans' view of the situation, decided how to respond, and then reacted before the Germans knew what they were up to.

The British thus had the advantage, but they then had to answer the Perennial Question of Information Warfare. Even Indian faced the Perennial Question when they first discovered a rival tribe using smoke signals. it sill confounds information warriors even today: Deny, deceive, destroy, or exploit? Do you transmit your own smoke signals to interfere with his? Do you send bogus signals to confuse your adversary so that he is easier to kill? Do you find the enemy sending the message and kill him? Or do you quietly watch the signals so you know where your adversary plans to be, head him off, and kill him then?

If the Brits jammed the beams or destroyed the radio stations, they might have eliminated the beam system temporarily. The Germans, however, would then have known that their guidance system was successful, or at least successful enough that the British believed they needed to neutralize it. Some German program manager would likely have used this fact to justify a request to build new transmitters that were better hidden and transmitted on different frequencies.

On the other hand, if the British simply sent their fighters to protect the target designated in the deciphered message, some German bombers would have gotten through. Even worse, if a squadron of Spitfires or Hurricanes regularly appeared at the appointed place night after night, the Germans would have eventually figured out that the British had cracked the cipher, which was about the most valuable secret the British had at the time.

This question of how best to attack an information system once you have the advantage—and who should do it—is an old one. Even today it is good for countless interagency meetings and memoranda. The Indian tribes probably had strategy meetings to deliberate how to deal with the smoke signal threat. One warrior likely proposed killing the signal senders, leaving their rivals blind, while another argued passionately for using the information to lay an ambush for the enemy braves who were being directed by the signals.

In the end, the British did a little of each. They jammed some of the signals some of the time, just enough to confuse the Germans. They bombed some of the radio stations. They even leaked some fanciful reports claiming that they had learned how to "bend" radio beams.

The goal was to keep the Germans off balance, and the plan worked. The Germans never lost confidence in their technology and kept using the same beam navigation system. By September 1940 the British had shot down 1,400 German aircraft. German bombing became less accurate. And Ultra, the secret intelligence based on the decrypted intercepts, remained secret until 1974, when the British government itself revealed its coup. 2

Even so, no one had really given much thought to how all these pieces—jamming, deception, intelligence—fit together. The really important thing was always the weapon-a gun or aircraft. Communications, tracking, and guidance were merely "support systems."

This was all about to change, thanks to other events underway in Seattle. As far back as 1851, when the city fathers convinced Henry Yesler to build his newfangled steam—powered sawmill along the banks of the Puget Sound, Seattle had risen, and fallen, on each new wave of technology. After Bill Boeing built his first seaplane for the Navy in 1917, the new technologies driving the Seattle economy were mainly based on aerospace—first airmail, then bombers, and more recently, missiles and satellites.

In the 1960s a new technology began to drive the Seattle economy: computers. Up to then, computers were scarce and expensive, and could only run one program at a time. **Then in 1957 a young mathematics graduate student named John McCarthy proposed a revolutionary idea: time-sharing, or having a single computer run several programs simultaneously.** This completely changed the computer business and, by extension, Seattle.

McCarthy, who was visiting MIT on a fellowship at the time, observed that the slowest part of a computer system is always the person operating it. We work at human speed; the computer works at electronic speed. The computer requires just milliseconds to run a typical calculation. McCarthy, later a distinguished professor in computer science at Stanford, realized that if you can collect computer jobs from many users, the computer can electronically rack-and-stack the jobs as they arrive, perform the operations as capacity becomes available, and thus run more or less continuously. 3

A Teletype—a typewriter that transmits a different electronic signal for each character in the alphabet—made it possible to do all this from miles away. The basic idea for the Teletype had been kicking around since 1909, but it was not until 1931 that the Bell System had introduced it into computers.

It did not take long for some early entrepreneurs to put all the pieces together and see a business opportunity. One could buy a computer, hook users into it with Teletypes, and sell portions of the computer's capacity to companies that couldn't afford to buy their own.

Time-sharing became popular at universities, which typically had two or three large computers located somewhere on campus, and tens of thousands of faculty and students who wanted to use them. S**o it was little wonder that many of the people who tried to get into the timesharing business were college staff, like Monique Rona.**

By then Monique had expanded her repertoire from oceanography to computer science. Soon she found herself running the university's computer center. Tom helped with the financing and Monique got together with some university colleagues to buy a Digital PDP-10. They set up the Computer Center Corporation—C-Cubed, for short—in an office near the campus. Monique put a Teletype on the kitchen table, and they were in business.

The PDP-10 had just hit the market. Being a new machine, it was prone to electronic burps and hangfires. The C-Cubed partners thought they might cut a deal where Digital would give them a discount on the computer if they worked out the bugs.

As it happened, one of the Rona boys attended the Lakeside School, a local private academy, and had heard of some classmates who liked to work with computers. Some of the Lakeside moms had bought their kids a Teletype and a few thousand dollars of computer time from local companies with money raised from a rummage sale. The moms hoped their kids might learn a few computer skills writing programs to play ticktacktoe and the like.

The kids had other ideas. They began playing with the Teletype day and night, taking apart programs and writing some of their own. In no time they burned through the computer time their mothers had bought them and had to look for some new benefactors, just when Monique was looking for some eager minds

to test her PDP-10. The boys cut a deal with C-Cubed: the boys would look for bugs in the PDP-10, and C-Cubed would give them some time on its computer.

Two of the kids, Bill Gates and Paul Allen, seemed to have a knack for computers. When the machine crashed, they would fetch the "core dump" from the trash and search through the machine language line by line to find the bug. They wangled operating manuals from the staff. Eventually the "Lakeside Programmers Group" came to know the insides of the PDP-10 about as well as C-Cubed did. So, when they ran out of their allotted time on the machine, they naturally took the simple expedient of fiddling with the computer's operating system to set back the clocks. Bill, Paul, and their Lakeside buddies Ric Weiland and Kent Evans were four of the earliest computer hackers. 4

Alas, the market for computer time-sharing never worked out as well as Monique had hoped, and C-Cubed eventually went broke, another case of roadkill on the path to IT riches. Gates and Allen went on to other ventures. One was a new company, "Micro-Soft," which they incorporated in April 1975 to sell programs for the Altair 8800, the first personal computer.

Meanwhile, Tom and Monique had that Teletype on their kitchen table. Computers—especially computers that talked with other computers—were part of the family. Tom could see that the Teletype in the Rona kitchen communicating with the PDP in the C-Cubed office near the university was no different than, say, a radar off the coast of New Jersey communicating with a central computer at the North American Air Defense Command in Colorado.

Rona could see that any widget that collected, moved, or processed data was part of a system, each dependent on the other. He could also see that every widget in a system was a potential point of vulnerability, as was the information that passed through them. These so-called support systems were potentially a better target than the weapon itself.

This had not occurred to anyone before, probably because information machines had never routinely talked to one another before. But what Rona now saw was clear: Control the information flowing through your adversary's computers and communications networks, and you could control the outcome of a battle or a war. Or, as Rona's monograph, Weapons Systems and Information War , put it, "Countermeasures aimed at the external flow of information will be further improved to the point that they may well become crucial in influencing the outcome of future engagements.—" 5

Often, in common English, this meant that the best way to defeat your enemy was to attack the components of its information systems, and Rona was broad-minded in defining "component." It included the hardware, of course, but it could just as easily be software, the people operating the system, the people getting the information out of the system, or the data that traveled through it. The best component to attack depended on the opportunities at hand and the risks one was willing to take.

In fact, Rona said, information war offers a major advantage over the old-fashioned kind. In information war, you have a menu of options—that Perennial Question of deny, deceive, destroy, or exploit? It offers an entire matrix of potential pressure points and methods for attacking the enemy. And if your target happens to figure out what you are up to, you can change tactics. The only challenge is to adapt faster than your adversary.

Boeing published Rona's monograph in the summer of 1976 as a "think piece" for company staff and customers. Tom Rona was the first person to use the term "information war" in print. Considering that the Internet was still thirteen years away and a "home computer" was something you built from a box of components with a screwdriver and a soldering gun, it was not a bad piece of prognostication.

Chapter 4 THE ASYMMETRIC WARRIOR

Many people think that information warfare—in particular, the idea of attacking computer networks—was the Defense Department's version of the dot-com boom. Some even believe that information warfare is like the management theories of Enron or Worldcom, a fashionable notion that will not last. But that is a faulty reading of history.

The origins of computer wars have a lot more to do with the Cold War of the 1980s than with the browser wars of the 1990s. The drafters and planners for information warfare were mostly Navy and Air Force officers who worried about fighting a nuclear war with the Soviet Union. Even the rationale for information warfare was originally a grand strategy aimed at toppling the Soviet empire.

To understand all this, one needs to go down the Pacific coast from Tom Rona's Seattle to Santa Monica, California, where the Air Force set up Project RAND in 1946 as one of the first not-for-profit think tanks. Project RAND was partly a leftover from World War II and partly preparation for the Cold War.

Planning a strategic bombing campaign is a lot like planning public works in reverse. Instead of building infrastructure to promote economic growth, the goal is to destroy infrastructure to kill an economy. The methodologies are even similar. You can run an industrial flow analysis to identify a manufacturing choke point and make a factory more efficient. Or you can run a flow analysis to identify a single point failure that will cause the whole plant to shut down when you blast it to bits.

From an analyst's point of view, this is really interesting work. Dismantling a country's infrastructure from 30,000 feet is usually a problem with several potential solutions: How many bombers? What kinds of bombs? Which targets? What is the optimal attack sequence?

During World War II the Army Air Corps recruiters - that is, drafted - economists, engineers, mathematicians, and assorted big-picture thinkers to analyze these problems.

After the war General H. H. "Hap" Arnold, the soon-to-become chief of the soon-to-be-created U.S. Air Force, knew he would need the same kind of eggheads. Unfortunately, the Air Force would have a hard time competing with universities and corporations for this talent in peacetime. And, truth be told, they were an odd fit for a uniformed service in any case.

That was the reason for Project RAND (Research and Development). At first, the Air Force put Project RAND inside the Douglas Aircraft Company. The operation got started just a month after the end of the war, as RAND set up shop in the Douglas Aircraft plant in the Santa Monica municipal airport.

The Air Force soon realized RAND would analyze proposals for all kinds of Air Force projects—including, most likely, aircraft and missiles proposed by Douglas Aircraft. Everyone knew this was an obvious potential conflict of interest. So in 1948 the Air Force spun off Project RAND into a nonprofit corporation. The new company continued to grow, and it soon moved to an office complex two blocks from the beach—a stone's throw from the Santa Monica Pier and conveniently situated next to Chez Jay, a local bar and hideaway.

Andrew W. Marshall was one of the early hires. Marshall started out publishing papers with ferociously academic-sounding titles on basic statistical theory ("Some Tests for Comparing Points of Two Arbitrary Continuous Populations") and methods for assessing the effectiveness of bombing operations ("The Estimation of Parameters in a Physical Vulnerability Model"). Soon, though, Marshall began to focus on bigger questions, like how to

measure the military capabilities of the United States and the Soviet Union and, by implication, how to tilt the balance in our favor.

Marshall soon found a theme that he would return to repeatedly over the next fifty years: "asymmetric threats." At the time, most people measured the so-called superpower arms race by comparing apples to apples.

Marshall saw that such comparisons were usually irrelevant because you usually needed to compare apples to oranges. Comparing the number of tanks the Soviets had to the number of tanks we had told you nothing, said Marshall. Neither did comparing the size of their missiles to the size of our missiles. The reason was simple. Countries playing offense need different weapons from countries playing defense.

Think of it this way: If you are attacking a castle, you need ladders to climb walls, battering rams to smash in the front gate, and shields to protect you from the arrows that the defenders will shoot at you from the parapets. If you are defending the castle, you need arrows to shoot down at the attackers, vats of boiling oil to pour on their heads, and so on.

So it doesn't mean anything to count the number of siege ladders on each side. This may seem painfully obvious today, but it was new for many politicians, generals, and pundits who were accustomed to thinking the strategic balance was something you read off a scorecard to see who was ahead.

To complicate matters further, the Soviet Union and the United States had different strengths to draw on. For instance, the Soviets could build bigger missiles because they had better rocket engines. But U.S. missiles were more accurate because we had better guidance systems. So a missile-to-missile comparison was misleading.

The most interesting thing about asymmetric threats, though, was that even the strongest army or air force could have an Achilles' heel. Indeed, a country might create such vulnerability for itself and not even know it.

This was a point that eventually made Albert Wohlstetter famous. Wohlstetter, one of Marshall's colleagues, described the ultimate asymmetric threat, in which a critical flaw, astutely exploited by an opponent, could leave even the most powerful military force dangerously weak.

At the time, the U.S. Strategic Air Command had four or five times as many long-range bombers as its Soviet counterpart. However, Wohlstetter noted that most U.S. aircraft were parked out in the open on airfields or, even worse, at foreign bases that were within range of a pre-emptive strike by the Soviet air force.

If the Soviets got the first punch, Wohlstetter said, they could destroy most of the U.S. bomber fleet. In fact, our vulnerability, combined with their own weakness, gave them an incentive to strike first if U.S.-Soviet relations went sour. This was really perverse, because the whole point of U.S. nuclear forces was to deter a Soviet attack. Wohlstetter claimed that, as configured, the U.S. force was not only failing to deter; it might even provoke a Soviet strike.

Usually the best army for winning a war bore little resemblance to the army that it had to defeat. They were, in other words, asymmetric. The ultimate goal, said Marshall, was finding the links in an opponent's forces that were not only weak, but which he couldn't fix even if he tried. Now that was really an asymmetric threat. It was the way to win not just a battle but the whole superpower competition.

Marshall knew that the idea of asymmetric threats was not only correct, it was impeccably logical. In fact, it was elegant. If you were defending, it revealed the vulnerability that others had overlooked. If you were on the offense, it could lead to a new strategy that was irresistibly efficient.

Marshall continued to work on measures of military capabilities until 1971. By then he had been at RAND for more than two decades. It wasn't a great time. The United States was en route to losing the Vietnam war, and it seemed that everywhere you looked in the developing world, some country was setting up a Marxist government or signing a "Friendship and Cooperation Treaty" with the Soviets. The United States badly needed a strategic solution—elegant, efficient, or otherwise.

The Soviet Union had pulled even in the superpower competition—or ahead, depending on how you measured it. Of course, measuring and comparing military capabilities happened to be Marshall's specialty. So, he asked, even if the situation looks bad now, can the United States plan a strategy that wins in the long run? To borrow a term from the economist David Ricardo, the United States needed to find its "comparative advantage," the areas in which it had a natural edge over the Soviets.

Computers seemed promising. A totalitarian country like the Soviet Union had to control the flow of information. The Soviet regime was so worried about the threat of samizdat that in 1971 the average citizen could not get near a Xerox machine, never mind a computer. This was a weakness that would help destroy the Soviet Union, although most Soviet leaders did not appreciate it at the time. The Kremlin's information technology phobia allowed the United States to plot a strategy that would emerge in full bloom during the Reagan administration and eventually push the Soviet Union over the edge.

Because the Soviets were so obsessed with controlling information, they could never have their version of Bill Gates and Paul Allen. The very idea of two teenagers foraging for free computer time on some company's PDP-10 was utterly nonsensical in the Soviet context. There were no computers in the private sector. For that matter, there was no private sector. All of the computers in the Soviet Union resided in state-sponsored research institutions and military bases, where they were protected behind security perimeters defined by fence lines three-deep.

The business world was beginning to outpace the government in developing new information technology. Marshall could see that as long as the Communists remained communists, the Soviets would never catch up. The United States, said Marshall, had to figure out some way to use this advantage. 1

As it happened, James Schlesinger—a RAND alum himself—became Secretary of Defense two years later and found himself searching for someone to head an "Office of Assessment and Strategic Planning." Schlesinger had discovered he had no one in the Department of Defense with the responsibility to step back now and then, look at the world, and estimate who was ahead, who was behind, and suggest what the Defense Department could do about it. He called his old colleague Andy Marshall, and Marshall moved to Washington.

"When we brought the office here, we concentrated on the assessment part and left off the strategic planning," Marshall recalls, smiling because he knew which part would likely have the greater influence. Thus began the Office of Net Assessment

"We got hold of some classified writings about how the Russians calculated the correlation of forces," he continues. "We were interested in reconstructing their calculations so that we could see how we might influence them." In other words, Marshall planned to find out how the Soviets decided whether they were ahead or behind in the superpower competition, and then mess around with their minds.

The Soviets seemed especially interested in computers and communications systems and how to attack them. Soviet writers recalled how the Red Army prevailed in World War II through radioelektronaya bor'ba , "radio-electronic combat."

Censorship was so strict in the Soviet Union that Soviet military writers often had to use analogies and examples from the Great Patriotic War to make their point. According to the Soviets, there were four basic techniques in radio-electronic combat: jamming an opponent's communications, using radio direction finding to direct artillery that would destroy the enemy, concealment, and inserting disinformatzia into the adversary's circuits to confuse him. 2

The Soviet writers were worried. According to their calculations, U.S. soldiers were better radioelektronaya bor'ba warriors than they could ever hope to be. They had taken a look at the American electronics industry and the systems that the Defense Department had deployed, and concluded that U.S. war planners must have given the topic a lot of careful thought

As it turned out, they were mistaken. "They thought that we were going to attack their command and control systems, even though our capabilities to do so were really not well developed," Marshall recalls. But this didn't matter. "The important thing was that they thought we were in a radio-electronic revolution, and then screwing them."

So Marshall began in 1978 to draft a Net Assessment on Command and Control. "The more we looked at it, the more we could see that the center of the change in warfare was in the sensors and the information systems. The information aspect of weapons had always been important, but now it was more important than ever. So one of your key operational goals had to be to establish an advantage," Marshall recalls.

Before long Marshall heard about Rona's monographs on "information war" at Boeing. The two met and hit it off. Marshall could see Rona was onto something. "No doubt about it. Tom was the first person to put it all together," recalls Marshall. **For the next four years Marshall supported Rona's work on the theory and practice of information war, or, as it came to be called, information warfare.** It was a bargain, as Boeing still picked up half of Rona's salary. 3

NOTES - Tom Rona left Boeing on March 1984 ..

As one connection led to another, Rona himself came to Washington a few years later. Ben Plymale, a vice president at Boeing and former defense official from the Nixon administration, was Rona's friend and mentor. Plymale introduced Rona to William van Cleve, a professor at the University of Southern California. Van Cleve had been an adviser to Ronald Reagan during the 1980 campaign and was directing the Defense Department transition team for the new administration. Rona started working for van Cleve, and soon caught the eye of [William Robert Graham (born 1937)], who was also working on the transition and was about to become Reagan's new director of the White House Office of Science and Technology Policy. Graham offered Rona a job as deputy director.

After Rona's stint in government, he remained the rest of his life as a Washington writer, consultant, savant, and bon vivant to an informal band of mid-level officers and officials on their way up. In coining the term "information warfare," Rona defined the most important factor in modern military thinking. And it was all because he could not afford to be an assistant professor at MIT, and Boeing was willing to pay him to think of new big ideas that would eventually sell more airplanes and missiles.

If anyone had told Tom Rona that his inventing information warfare was originally just a hook for selling Boeing's electronic widgets, he probably would have appreciated the irony. After all, the power to shape the actions of a military organization is the whole idea of information warfare. And that was exactly what Rona did. But if you caught Tom Rona in a quiet moment, he would likely say that he would be satisfied if he had just discovered some way his adopted country could avoid all the chaos that he had seen in his own life.

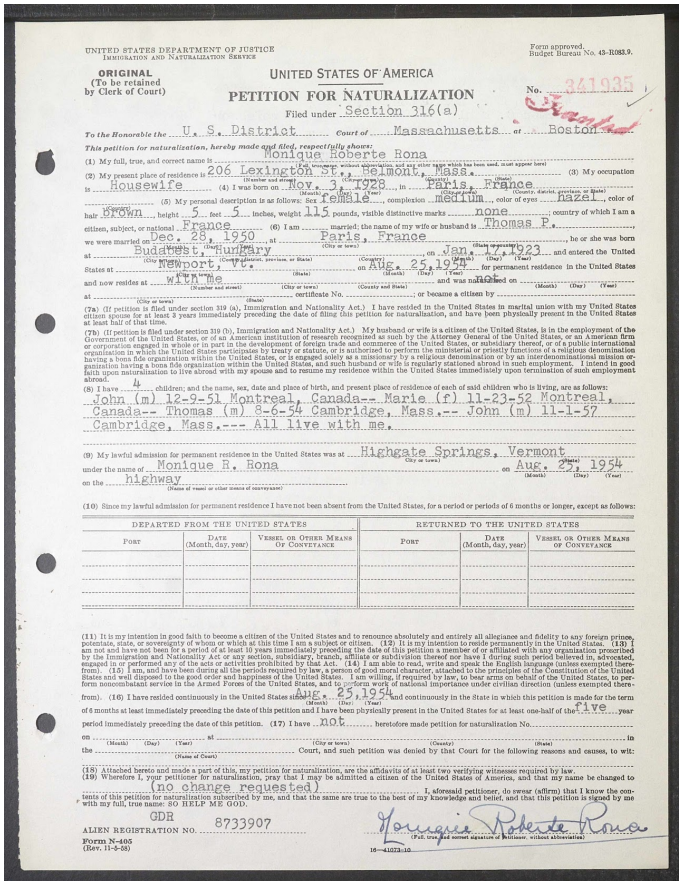
1954 - US Naturalization Petition



UNITED STATES DEPARTMENT OF JUSTICE
IMMIGRATION AND NATURALIZATION SERVICE

Form approved.
Budget Bureau No. 43-R083.9.

ORIGINAL
(To be retained by Clerk of Court)

UNITED STATES OF AMERICA

PETITION FOR NATURALIZATION

No. 341935

Filed under Section 316(a)

To the Honorable the U. S. District Court of Massachusetts at Boston

This petition for naturalization, hereby made and filed, respectfully shows:

(1) My full, true, and correct name is Monique Roberte Rona
(Do not use initials without explanation; if a nickname is used, insert proper name which has been used, in full, after other name which has been used, in quotation marks)

(2) My present place of residence is 206 Lexington St., Belmont, Mass. (3) My occupation is Housewife

(4) I was born on Nov. 3, 1928 in Paris, France
(Month) (Day) (Year) (City or town) (Province, district, province, or State) (Country)

(5) My personal description is as follows: Sex female, complexion medium, color of eyes hazel, color of hair brown, height 5 feet 5 inches, weight 115 pounds, visible distinctive marks none; country of which I am a citizen, subject, or national France

(6) I am married; the name of my wife or husband is Thomas P. ; we were married on Dec. 28, 1950 at Paris, France, he or she was born at Budapest, Hungary on Jan. 17, 1923 and entered the United States at Newport, Vt. on Aug. 25, 1954 for permanent residence in the United States and now resides at with me at certificate No. ; or became a citizen by

(7a) (If petition is filed under section 319 (a), Immigration and Nationality Act.) I have resided in the United States in marital union with my United States citizen spouse for at least 3 years immediately preceding the date of filing this petition for naturalization, and have been physically present in the United States at least half of that time.

(7b) (If petition is filed under section 319 (b), Immigration and Nationality Act.) My husband or wife is a citizen of the United States, is in the employment of the Government of the United States, or of an American institution of research recognized as such by the Attorney General of the United States, or an American firm or corporation engaged in whole or in part in the development of foreign trade and commerce of the United States, or subsidiary thereof, or of a public international organization in which the United States participates by treaty or statute, or is authorized to perform the ministerial or priestly functions of a religious denomination having a bona fide organization within the United States, or is engaged solely as a missionary by a religious denomination or by an interdenominational mission organization having a bona fide organization within the United States, and such husband or wife is regularly stationed abroad in such employment. I intend in good faith upon naturalization to live abroad with my spouse and to resume my residence within the United States immediately upon termination of such employment abroad.

(8) I have 4 children; and the name, sex, date and place of birth, and present place of residence of each of said children who is living, are as follows:
John (m) 12-9-51 Montreal, Canada-- Marie (f) 11-23-52 Montreal, Canada-- Thomas (m) 8-6-54 Cambridge, Mass.-- John (m) 11-1-57 Cambridge, Mass.--- All live with me.

(9) My lawful admission for permanent residence in the United States was at Highgate Springs, Vermont under the name of Monique R. Rona on Aug. 22, 1954 on the highway

(10) Since my lawful admission for permanent residence I have not been absent from the United States, for a period or periods of 6 months or longer, except as follows:

DEPARTED FROM THE UNITED STATES			RETURNED TO THE UNITED STATES		
Port	Date (Month, day, year)	Vessel or Other Means of Conveyance	Port	Date (Month, day, year)	Vessel or Other Means of Conveyance

(11) It is my intention in good faith to become a citizen of the United States and to renounce absolutely and entirely all allegiance and fidelity to any foreign prince, potentate, state, or sovereignty of whom or which at this time I am a subject or citizen. (12) It is my intention to reside permanently in the United States. (13) I am not and have not been for a period of at least 10 years immediately preceding the date of this petition a member of or affiliated with any organization proscribed by the Immigration and Nationality Act or any section, subsidiary, branch, affiliate or subdivision thereof nor have I during such period believed in, advocated, engaged in or performed any of the acts or activities prohibited by that Act. (14) I am able to read, write and speak the English language (unless exempted therefrom). (15) I am, and have been during all the periods required by law, a person of good moral character, attached to the principles of the Constitution of the United States and well disposed to the good order and happiness of the United States. I am willing, if required by law, to bear arms on behalf of the United States, to perform noncombatant service in the Armed Forces of the United States, and to perform work of national importance under civilian direction (unless exempted therefrom). (16) I have resided continuously in the United States since Aug. 25, 1954 and continuously in the State in which this petition is made for the term of 6 months at least immediately preceding the date of this petition and I have been physically present in the United States for at least one-half of the five year period immediately preceding the date of this petition. (17) I have not heretofore made petition for naturalization No. in on M. in the Court, and such petition was denied by that Court for the following reasons and causes, to wit:

(18) Attached hereto and made a part of this, my petition for naturalization, are the affidavits of at least two verifying witnesses required by law.
(19) Wherefore I, your petitioner for naturalization, pray that I may be admitted a citizen of the United States of America, and that my name be changed to (no change requested)

I, aforesaid petitioner, do swear (affirm) that I know the contents of this petition for naturalization subscribed by me, and that the same are true to the best of my knowledge and belief, and that this petition is signed by me with my full, true name: SO HELP ME GOD.

AFFIDAVIT OF WITNESSES

The following witnesses, each being severally, duly, and respectively sworn, depose and say:

(1) My name is Dorothy S. Dahl, my occupation is Housewife
I reside at 40 Fern St., Lexington, Mass. and

(2) My name is Norman C. Dahl, my occupation is Professor
I reside at 40 Fern St., Lexington, Mass.

I am a citizen of the United States of America; I have personally known and have been acquainted in the United States with the petitioner named in the petition for naturalization of which this affidavit is a part, since at least August 27, 1954 to my personal knowledge the petitioner has resided, immediately preceding the date of filing this petition, in the United States continuously since the date last mentioned; that the petitioner has been physically present in the United States for at least 31 months of that period; and that the petitioner has been a resident in the State in which the petition is filed during at least the last 6 months. I have personal knowledge that the petitioner is, and during all such periods has been a person of good moral character, attached to the principles of the Constitution of the United States, and well disposed to the good order and happiness of the United States, and in my opinion the petitioner is in every way qualified to be admitted a citizen of the United States.

I do swear (affirm) that the statements of fact I have made in the affidavit to this petition for naturalization subscribed by me are true to the best of my knowledge and belief: SO HELP ME GOD.

Combined Chlorophyll and Productivity

Language - FORTRAN IV
Hardware - CDC 6400

Computes assimilation of productivity in seawater; also computes the quantities of chlorophyll A, B, and C, and the amount of carotenoids in seawater. The chlorophyll program determines the amount of plankton pigments using the equations of Richards and Thompson. The productivity program (Carbon 14) determines the production of marine phytoplankton by using Neilsen's method. Output consists of both printed matter and of library cards; the cards may be used as input to a multiple regression program to derive a relation between productivity and chlorophyll A; a plot routine may be called to graph one or several variables as a function of depth, or to display the horizontal distribution of any given property. Written by Marsha Wallin, Nov. 1963, based on two programs prepared in 1962 for the IBM 709 by M.R. Rona; revised in 1969 for the CDC 6400.

DISTRIBUTION OF BEACH SEDIMENT NEAR
THE COLUMBIA RIVER

ABSTRACT

The coastline near the Columbia River, between Tillamook Head, Oregon and Grays Harbor, Washington, is characterized by prograding beaches in contrast to the rest of the Washington-Oregon coast where actively eroding sea cliffs are present. The Columbia River appears to be the major contributor of sediment to the beaches and probably accounts for their prograding character. Littoral transport of material from coastal erosion probably has some effect on the sediment budget, but coastal barriers of promontories and estuaries limit influx of this material. Some material is added to the beach as a result of jetty breakdown, especially near Grays Harbor, Washington. Willapa Bay apparently contributes only minor amounts of sediment to the area.

The net direction of beach sediment movement near the Columbia River appears to be northward. Seasonal changes in the direction of wave attack complicate the analysis, but the greater energy associated with winter wave conditions is directed northward and probably results in a predominant northerly sediment movement. Mechanical and heavy mineral analyses are consistent with the results of wave studies.

Computers within the Department of Oceanography

It was decided that Oceanography should have its own sea going computer**. A PDP-5 was purchased and installed on the RV Brown Bear in the August 1964. *Monique Rona* and *William Walker* were the principal operators.** The input-output device was a teletype. No more IBM cards. What was proven by this experiment was that a computer worked very well at sea and was a valuable tool. But the operator frequently rode the rail. When the first **RV T. G. Thompson** arrived in December 1965, the Department purchased two IBM-1130's, one for land and one for the ship. This proved to be a very satisfactory addition. The 1130 used a 16-bit word and had 8K of memory. Within a year, 8K more memory was added. This consisted of a rack mounted panel 19" wide, 8" high, 20" deep and cost $10,000. We know had 16K words of memory and could write larger programs. Because of the limited memory, which we thought of as huge, we used many overlays. Again the language used was FORTRAN. IBM had written many FORTRAN subroutines to handle alphabetic characters, thus increasing the usefulness of this computer. [...]

Preface

Findings presented in this paper are based upon field observations collected as part of the Coast and Geodetic Survey's oceanographic survey program of the central North Pacific Ocean. The paper was prepared originally as a thesis in partial fulfillment of the requirements for the degree of Master of Science in oceanography at the University of Washington, Seattle, Wash., in 1964. As a thesis, the paper was titled "Deep Circulation in a Portion of the North Pacific Ocean During the Summers of 1961, 1962, and 1963." The author, who participated in the North Pacific Ocean survey during 1961, 1962, and 1963, is grateful for the opportunity afforded him by the Coast and Geodetic Survey to pursue graduate study in oceanography at the University of Washington. He would like to acknowledge the interest and support shown by the faculty and staff of the Department of Oceanography at the university during preparation of the thesis—particularly Dr. Clifford A. Barnes for helpful guidance, Dr. Maurice Rattray, Jr., for critical review, Mrs. Monique Rona for machine processing of data, and Mr. Donald R. Doyle for preparation of illustrations. Machine processing of data and preparation of drawings were supported in part by the U.S. Office of Naval Research (Contract Nonr 477–10, Project NR 083012). The paper is published in its original form except for editorial revision of format. Illustrations are grouped at the end of the paper. The list of symbols is in appendix III.

1968 - The United Nations Treaty Series Project / PETER H. ROHN UNIVERSITY OF WASHINGTON / Source: International Studies Quarterly , Jun., 1968, Vol. 12, No. 2 (Jun., 1968), pp. 174- 195

Source : [HP003Y][GDrive] (Note - Purchased for 39 dollars , Nov 2020)

[...]

1963. *The United Nations Treaty Series Project (UNTS Project) started as a vague hunch in a class discussion. The question was how to prove the growth of international institutions in conventional international law. The answer was simple in theory but difficult in practice. We should survey the texts of treaties. If references to international institutions increased, the point was proved; otherwise, disproved. The more treaties we surveyed the more reliable the results would be. There was no money to pay for anything, no special equipment, no extra work space, nothing but the idea and the library and a group of students volunteering to do the job as part of their classwork in international law.*

Two months later, some fifty students had combed through all volumes of the United Nations Treaty Series (UNTS). There were 426 volumes in the autumn of 1963. A few key characteristics were extracted from every one of the 6,734 treaties published up to that time in the UNTS. The students coded these key characteristics on dittoed code sheets. By Christmas I had on my desk a pile of several hundred code sheets filled out by 50 students in as many handwritings. I had no way of guessing the level of accuracy and completeness, let alone usefulness, of the whole exercise.

[...][page 178][...]

Also in 1965, the UNTS Project became part of the regular graduate instruction in international law at the University of Washington. A system was developed (and is still in force) whereby seminar students must combine traditional and quantitative methods in international law. Standard procedures include the handling of UNTS Project printouts, code manuals, and raw data cards. Students also use auxiliary equipment in the computer center as well as desk calculators and other simple devices for minor individual tasks. Measurements and computer-oriented activities must be related to traditional research wherever possible.

1966. *This year saw a gradual shift of emphasis from investment to production. Data enlargement continued by adding identifications of international organizations referred to in treaty texts and identity of registering party, as well as some refinements in the 1965 topic code. The second annual updating was completed in June by adding to the data bank UNTS Volumes 454-503 published between June 1965 and June 1966. Data enlargement and updating having become a routine function of an on-going operation, the main thrust of the work in 1966 concerned new programs for the machine-handling of UNTS data, and analytic work in selected aspects of the law of treaties. Completed were the study of the Canadian UNTS Gap," a special study on the role of military matters in the world's treaty pattern,[12] a general statement of theoretical under- pinnings for the UNTS Project, [13] a paper on information retrieval aspects of the UNTS Project, [14] and an outline of a more general scheme of computerizing international law. [15]*

Two professional meetings on the use of computers in international relations research included the UNTS Project: (1) the special working group on electronic data processing set up by the American Society of International Law; [16] and (2) the Institute on "Computers and the Policy-Making Community" sponsored by the Endowment for International Peace and the U. S. Atomic Energy Commission. [17]

Also in 1966, two graduate student papers on UNTS Project material attracted professional interest: (1) one paper was selected for presentation to a West Coast regional conference [l8] and was then revised and published elsewhere; [19] and (2) the other paper was chosen for presentation to the University of Washington Student International Law Society and then also published elsewhere. [20] By the end of 1966, a total of 15 students found their work referred to by name in UNTS Project publications,[21] and 8 of them more than once. [22]

Finally, the UNTS Project was given a broader institutional base at the University of Washington through the appointment of a joint advisory committee by the Dean of the Law School and the Chairman of the Political Science Department.

1967. *Three new sets of data were added in 1967: (1) date of effect, (2) date of registration and (3) official languages. New work began on multilateral treaties and on treaty history subsequent to registration, e.g. prolongations, terminations, accessions, withdrawals, amendments, and reservations. The annual updating proceeded concurrently with the addition of new data. UNTS Volumes 504-550 were coded. This brought our data bank up to date, covering all UNTS volumes published through December 1967.*

The computer center started developing for the UNTS Project a teletype capacity for instant retrieval between the UNTS Project office and the computer center. This is being done by means of the B-5500 XTAB retrieval program adapted by the computer center of the University of Washington especially to the needs of the UNTS Project. It will be used in addition to the existing capacity of the IBM-7094 for both retrieval and computation. The B-5500 program plus teletype response will cut the waste and the waiting time involved in using the IBM-7094 (or later the IBM-360) for simple retrieval jobs. ***[23][Grateful recognition for imaginative help far beyond routine cooperation is made to the two co-directors of the computer center at the University of Washington, David Dekker and Carl Young, and to the following staff members in particular: Charlene Haug, Elton Hay, Larry Menninga and Monique Rona.]*** *Hunches can then be tested in minutes rather than days. Retrieval also has become a somewhat larger part of UNTS Project operations as more faculty and graduate students use our data bank and as more requests for special data printouts are received from outside. [24]mm[...]*

1968-08-14-the-seattle-times-pg-35-clip-computer-center

Computer Firm Formed

A new computer firm, the Computer Center Corp., has been formed by four University of Washington specialists, it was announced today.

Carl G. Young, director of operations at the university's computer center since 1965, has resigned to become president of the new company, which will specialize in service to scientific firms and industries on a time-sharing basis.

Quarters have been leased in the former Dresslar-Waesche Building at 4057 Roosevelt Way N. E.

Dr. David B. Dekker, who has been faculty director of the University Computer Center since its establishment, is vice president of the new firm.

DEKKER will serve in a consultant capacity during the school year and continue on the university faculty as an associate professor of mathematics and graduate-program adviser in computer sciences. He has resigned his position with the University Computer Center.

C. G. YOUNG

DR. D. B. DEKKER

Richard G. Hamlet, chief systems programmer at the University Computer Center, and Monique R. Rona, chief scientific programmer at the center, have resigned their university positions to join the new firm.

A fifth incorporator is Richard L. Wilkinson, formerly Northwest sales manager of the Digital Equipment Corp.

TIME-SHARING of the capabilities of large, fast and complex central processors will be the principal mode of operation of the corporation, Young said.

The company plans to sell computer time via common-carrier lines from teletype machines or other electronic typewriter devices situated in customer offices.

The user will be able to communicate data directly to the computer and receive almost instantaneous reply in his own office.

The Computer Center Corp. plans to be in operation about November 1.

Westside S & L Leads July Gain

Westside Federal Savings & Loan Association in July led a local reversal of the usual July trend toward a decline in net savings.

Net savings rose only $200,000 last month in the 23 associations affiliated with the Seattle League of Insured Savings Associations. Westside, a member of the association, registered a gain of $433,000.

In 1966, when there was a tight money situation comparable to this year, league institutions suffered a July loss of $6.7 million.

Source : [HI001H][GDrive]

[...]

Kossow: All these vertically stacked platters.

Russell: Yeah. That was not as reliable as was desirable. But the main struggle was we just didn't get enough business. And so eventually they went out of business. And at that point, I guess I had annoyed DEC sufficiently that they thought maybe I would be useful in marketing. And so I started working for Digital.

Kossow: There's the one little story that you had a couple of testers up in Seattle.

Russell: Oh yes, yes. We did have a testing program. Was it TOPS-10 by then? I'm not sure. **At any rate, the multi-user operating system for the PDP-10 was not a paragon of reliability. In fact, it started out with a pretty dismal mean time to failure. And so we had a couple of people working on basically fixing, full-time, fixing bugs in the operating system. And there was no real lack of bugs to fix. Monique Rona had— was one of the principles, and her son was going to Lakeside School. And so she arranged that we could— we give some time to the Lakeside School who had got a teletype**. And we also had built a training room which had six or eight terminal teletypes in it. And what we would do is on Saturdays especially, we'd open that up to the Lakeside students to come in and load test the computer. We wanted lots of people. And the rules were, you can do anything you want, you can try to break the system if you want. But if you do manage to break the system, you've got to tell us what you did and don't do it again until we tell you. And this was quite fruitful. We collected heavy load bugs this way. And two of the students were Paul Allen and Bill Gates. And they had to be admonished several times about the "don't do it again until we tell you" part of the rules. But they certainly had a great deal of fun and they evidently learned quite a bit.

Kossow: You remember anything in particular that they did?

Russell: No. They asked lots of questions. And one of the things that we would do at Saturdays was, Dick Gruen or I or somebody would be in the terminal room, or periodically stick our nose in the terminal room, make sure that the pandemonium was under control, and answer questions." [...]

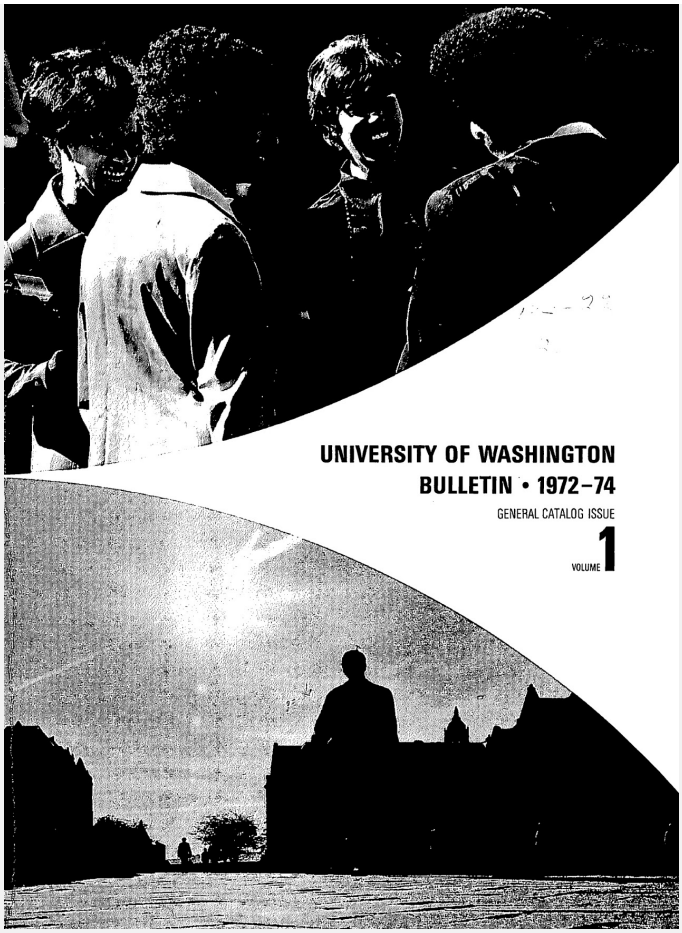
- Robert G. Gillespie , B.A., Director Computer Center SC-10 [See **Robert Gordon Gillespie (born 1933)**]
- Charles W. Dickens, Assistant.Director
- Scott A. Eyler, Assistant Director
- Monique Rona, Assistant Director

The Computer Center, established in 1956, provides computer services for the University of Washington and the community for education, research, and administrative uses. The principal. computers now installed include a Burroughs 5500 and .3. Control Data Corporation-6400. Also available are key-punch/EAM, auxiliary card-handling equipment with service provided for self-servi~ use; graphics equipment, including mechanical · plotting equipment allowing automatic plotting of information and a digital. recording system capable of reading coor:dinates from maps, graphs, film, etc., and recordiDg them on magnetic tape; and terminals which make possible text editing and remote job entry from teletypes directly connected to the B5500 and the CDC 6400.

[...]

The University of Washington Computer Center is equipped with a CDC 6400 computer system, a ,Burroughs-B5500, and miscellaneous supporting equipment.

Ii! provides compu~g services to all areas of the University and is also available. to all students. Robert G. Gillespie is the Director, Charles W. Dickens, Monique Rona, arid Scott Eyler are Assistant Directors of the Computer Center.



UNIVERSITY OF WASHINGTON
BULLETIN • 1972–74
GENERAL CATALOG ISSUE
VOLUME 1

[HE002W][GDrive]

During spring and summer, the Laboratories offer an opportunity for independent and supervised research, as well as a varied program of instruction primarily oriented to graduate students (exceptional, advanced undergraduates are occasionally admitted). Throughout the year, use of the facilities of the Laboratories for research in various areas of marine science is encouraged.

Requests for information on the summer program and for general information concerning study and research, availability of facilities, and admission to the Laboratories should be addressed to the Director, Friday Harbor Laboratories, 208 Kincaid NJ-15, University of Washington, Seattle, Washington, 98195.

Office of Scholarly Journals
Emily Johnson, B.A., *Director*
Parrington Annex 7

The University maintains an Office of Scholarly Journals in association with the Graduate School. The function of the Office is to provide assistance to members of the University faculty who have editorial responsibilities in relation to the publication of the many scholarly journals now associated with the University of Washington.

Requests for information concerning the activities and facilities of the Office should be addressed to the Director, Office of Scholarly Journals, University of Washington, Seattle, Washington 98195.

Computer Center
Robert G. Gillespie, B.A., *Director*

Monique Rona, *Assistant Director*

The Computer Center, established in 1956, provides computer services for the University of Washington and the community for education, research, and administrative uses. The principal computers now installed include a Burroughs 5500 and a Control Data Corporation-6400. Also available are key-punch/EAM, auxiliary card-handling equipment with service provided for self-service use; graphics equipment, including mechanical plotting equipment allowing automatic plotting of information and a digital recording system capable of reading coordinates from maps, graphs, film, etc., and recording them on magnetic tape; and terminals which make possible text editing and remote job entry from teletypes directly connected to the B5500 and the CDC 6400.

[HE002X][GDrive]

The Center offers specialized training through non-credit classes in programming languages and operating systems needed to use the computer systems in the Computer Center. Other services available are consultation; an information center that includes reference materials, computer manuals, and special program libraries; and professional programming.

Cost accounting and reporting is provided to the users for all computer services. The staff of the Center, in liaison with campus users, plans for special hardware and software requirements and develops general purpose computer programs satisfying major user requirements.

The Center is administered through the Office of the Vice President for Research.

Requests for the *Computer Center Newsletter* or for information concerning the facilities should be addressed to the Director, Computer Center, University of Washington, Seattle, Washington, 98195.

Computer Science Laboratory
Hellmut Golde, Ph.D., *Director*
43 Roberts Hall

The Computer Science Laboratory (CSL) is the research and teaching laboratory for the Computer Science Group. It is used for studies of operating systems and other computing project studies which, if done on Computer Center equipment, might impede the job flow; and for studies which require specialized equipment (e.g. graphics terminals) which are not supported by the Computer Center.

The operation of the Computer Science Laboratory is integrated with the graduate training program of the Computer Science Group in order to provide practical experience for those Computer Science students interested in the engineering and applied aspects of computer science. A large amount of time is reserved for open-shop operation for experimental studies.

The Laboratory contains a Xerox Data Systems Sigma 5 Computer with a disc-oriented operating system. A second component is the remote terminal system for interactive computing. The Laboratory also has facilities for computer graphics studies.

Division of Marine Resources
Stanley R. Murphy, Ph.D., *Director*
John Dermody, B.S., *Assistant Director for Operations*
3716 Brooklyn N.E., Apt. 3

The Division of Marine Resources promotes the University's interest in the exploration, development, and

it is recommended that the student admitted to the program in linguistics have completed the equivalent of 45 quarter credits (30 semester credits) of undergraduate college credits in language study. This requirement implies the attainment of proficiency in one language other than English or, in the instance of a non-native speaker of English, a course of study and proficiency in a language other than his native speech. To register for courses, students should consult with the Graduate Program Adviser in Linguistics.

PROGRAMS OF STUDY
Master of Arts
Requirements for the Master of Arts degree are as follows: (1) Familiarity with as many languages as possible; (2) 36 credits, with at least 18 credits in courses numbered 500 or above, including 9 credits for the thesis; (3) successful performance in a comprehensive examination in General Linguistics; (4) completion of a thesis acceptable to the student's committee; (5) attendance at a linguistic institute is strongly recommended.

Doctor of Philosophy
A student may be granted permission to proceed directly for the doctoral degree without an M.A., but the Department reserves the right to require any individual student to present himself as a candidate for the M.A. before accepting him as a prospective candidate for the Ph.D. Requirements for the Ph.D. include 36 credits in linguistics or supporting areas, in lieu of the M.A., plus the following (subject to readjustment by the student's Committee): Linguistics 599; 33 additional credits in linguistics or supporting areas, as approved by the Department; supervised teaching, in lieu of an examination, in first, phonology; second, syntax; third, historical-comparative linguistics; the oral General Examination, and finally, a dissertation suitable for publication and constituting a contribution to knowledge and the Final Examination.

Pincus, David L. Ragozin, Galen R. Shorack, Robert T. Smythe, Gomer Thomas, John W. Van Ness, Michael J. Westwater, Kenneth Whyburn, Daniel E. Wulbert

Lecturers
Kathleen B. O'Keefe, Helen C. Zuckerman

Traditionally, mathematics has been the basic language of physical science and engineering, but recently it has also become of major importance for students in social science, business administration, and biological sciences. Mathematics is also an essential element of a liberal education, and students from humanities and the arts are encouraged to broaden their education by enrolling in appropriate courses in the Department. The Department of Mathematics serves the University by offering a wide selection of undergraduate and graduate courses which are organized to meet a great variety of mathematical needs.

Mathematics is also a discipline in its own right, and interesting and profitable careers are open to students who specialize in the subject. In order to prepare students for these careers, the Department offers a wide range of degree programs including a general bachelor's degree, a specialized bachelor's degree, several master's degrees, and a doctor's degree. In addition to pure mathematics, programs are available in mathematical statistics, numerical analysis, and teacher education. The Department cooperates closely with the Department of Physics and the College of Engineering in providing instruction in the area of applied mathematics. Several departments offer courses which are of interest to applied mathematics majors. Particular attention is directed to certain graduate courses in the Department of Aeronautics and Astronautics.

[HE002Y][GDrive]

Special Facilities

The Center for Quantitative Science in Fisheries, Forest Resources, and Wildlife Sciences (Gerald J. Paulik, Director), provides a focus for applied statistical and mathematical activity directed particularly toward biological problems. Information on the applied statistics courses taught in the Center, most of which were formerly taught in the Mathematics Department, can be found in the section on the Center under the Colleges of Fisheries and of Forest Resources. The courses include Quantitative Science 382, 383, and 486 (formerly Mathematics 382, 383, and 486). Quantitative Science 281 is equivalent to Mathematics 281.

The University of Washington Computer Center is equipped with a CDC 6400 computer system, a Burroughs B5500, and miscellaneous supporting equipment. It provides computing services to all areas of the University and is also available to all students. Robert G. Gillespie is the Director, Charles W. Dickens, Monique Rona, and Scott Eyler are Assistant Directors of the Computer Center.

A graduate program in biostatistics leading to the degrees of Master of Science and Doctor of Philosophy is administered by the Graduate School Biomathematics Group. Faculty in the Department of Mathematics and certain other departments in the College of Arts and Sciences and certain departments in the School of Medicine cooperate in this program. Information concerning the program will be found in the *Interdisciplinary Graduate Degree Programs* section of this catalog.

A graduate program in computer science leading to the M.S. and Ph.D. degrees is administered by the Graduate School Computer Science Group. Faculty in the Department of Mathematics and certain other departments throughout the University cooperate in this program. Information concerning the program will be found in the *Interdisciplinary Graduate Degree Programs* section of this catalog.

Undergraduate Programs
Advisers
J. Maurice Kingston
C36B Padelford Hall

Kathleen B. O'Keefe
C36C Padelford Hall

Students planning to take courses in mathematics, either as mathematics majors, or as part of some other curriculum, are strongly advised to elect four years of mathematics in high school. Mastery of these four years of work will prepare them to enter Mathematics 124 (Calculus with Analytic Geometry), which is the

[HE002Z][GDrive]

first course of university level offered by the Department. Admission to this course is based upon high school records and either the Mathematics Achievement Test of the Washington Pre-College Testing Program or a placement test given by the Bureau of Testing. Students who have completed a full year of calculus in high school, preceded by accelerated study, are encouraged to take the Advanced Placement Test in Mathematics given by the College Entrance Examination Board or parts I and/or II of the Calculus Test given by the Bureau of Testing. Those whose scores on these examinations are satisfactory will be placed in Mathematics 125 or 126 and given university credit for the courses in calculus which they have been allowed to skip. Alternatively, these students may be qualified to enter the freshman honors course.

As a service to entering students who have had less than four years of high school mathematics, the Department offers the following courses which duplicate high school material: 101 (Intermediate Algebra), 104 (Plane Trigonometry), 105 (Elementary Functions). Mathematics 105 may be taken for University credit. In order to enter 105, students must have the high school prerequisites listed under the detailed course descriptions (see *Volume II, Description of Courses*), and must also obtain satisfactory scores on the Mathematics Achievement Test of the Washington Pre-College Testing Program. Mathematics 101 and 104 are offered without credit and are available only through the Division of Continuing Studies, upon payment of a separate fee.

In order to enter 105, students must have the high school prerequisites listed under the detailed course descriptions (see course descriptions in *General Catalog* Volume II) and also must obtain satisfactory scores on the Mathematics Achievement Test of the Washington Pre-College Testing Program.

GRADUATION REQUIREMENTS
Bachelor of Arts
The B.A. degree is designed for liberal arts majors who have only modest professional aims in mathematics. It also provides a suitable program for prospective high school teachers of mathematics. Grades in all mathematics courses to be counted toward this degree must be C or better, and a grade-point average of at least 2.00 in all mathematics courses must be maintained. There are two curricular options:

LIBERAL ARTS OPTION
A minimum of 50 credits in mathematics beyond trigonometry is required. Courses must include 124, 125, 126, 224, 205 or 302, and 28 or 29 credits in approved electives.

Marie Rona to Wed Steven Ross Maris

Miss Marie Helene Rona and Steven Ross Maris will be married in a ceremony at 3 o'clock Saturday afternoon at the University Presbyterian Church in Seattle.

The Rev. Ben Lindstrom of Portland, Ore., will officiate at the rite for the daughter of Dr. and Mrs. Thomas P. Rona, Seattle, and the son of Dr. and Mrs. Robert W. Maris, E1316 Twenty-sixth.

A reception will follow at the home of the bride-elect's parents.

Miss Janet Gwen Maris, sister of the future bridegroom, will be maid of honor.

Patrick Boileau, Portland, Ore., will serve as best man. Ushers will be Michael, Thomas and Chris Rona and Donald and Neil Maris, brothers of the couple.

The couple will reside in Seattle. The bride-elect will be graduated from the University of Washington in June. Maris is attending the U of W Graduate School of Business.

Monique Rona dies; Group Health official

Monique Roberta Rona, 46, of 5770 63rd Ave. N. E., died Sunday about four hours after she was injured in a two-car crash at 26th Avenue Northeast and Northeast 117th Street.

Mrs. Rona was eastbound in Northeast 117th Street about 6:45 p. m. when her car and a car southbound in 26th Avenue Northeast, collided.

The driver of the other car, Gerald Wayne Henneke, 31, of 5823 McKinley Pl. N., suffered nose and leg injuries but was not hospitalized, police said.

Mrs. Rona was head of information processing for Group Health Cooperative of Puget Sound. She was the wife of Dr. Thomas P. Rona.

A native of Paris, she came to Seattle 16 years ago, and for 14 years was deputy director of the University of Washington computer center.

She served on the Presidential Commission on Energy, and was an active member of the Association of Computing Machinery.

Two months ago she was named to the Group Health post.

Services are set for 3 p. m. Thursday at University Presbyterian Church. Home Funeral Chapel is handling arrangements.

In addition to her husband, Mrs. Rona is survived by four children, John, Mary, Thomas, Jr., and John Christopher, and by her mother, Gabrielle Noel, all of Seattle.

The family suggests remembrances to Medic I.

[HB004X][GDrive]

Chapter 3 “THEY ARE ALREADY AMONG US” To understand modern warfare, you need to begin, of all places, in Budapest.

[...] Much of the twentieth century’s brainpower was born within Hungary: John von Neumann, inventor of both quantum mechanics and the computer program; atomic scientists Edward Teller, Eugene Wigner, Leo Szilard, and Isidor Rabi; Elie Wiesel, humanitarian and recipient of the Nobel Peace Prize; Andy Grove, one of the founders of Intel Corporation. All were Hungarians. Or, more precisely, ex Hungarians. Budapest may resemble a fairyland. Its onion-domed churches and hot-spring fountains may seem enchanting. But the city has always had a dark side. Hungary is at the crossroads of Europe, another way of saying that it has been on the invasion routes connecting Germany, Russia, and Turkey.

Things got especially chaotic in Hungary after World War I, when the Allies carved up the Austro-Hungarian Empire, and got even worse after the Fascists and Communists began to compete for control. Eventually the Fascists won out, and Hungary sided with Nazi Germany during World War II. As a result, the U.S. Fifteenth Air Force flattened Budapest, and the Red Army pillaged what remained. The combination of a cosmopolitan society, a devotion to education, and a penchant for war and riot has made Hungary a leading exporter of human genius.

Among those fleeing all the chaos were Edward and Irene Rona, **who sent their son Thomas and his older brother George to the more tranquil environs of Paris soon after Tom was born in 1923. Tom grew up a Parisian, taking his finals in engineering at the École Polytech-nique on V-E Day. After a brief detour with the French engineering corps building bridges in Cameroon (partly to dodge an irate father and a shotgun marriage), Rona returned to Paris and met Monique Noel, a bank clerk. Tom and Monique soon married.**

Tom and Monique began moving farther and farther west to escape the chaos and constraints of the Old World—first to Montreal, then to a junior faculty position for Tom at the Massachusetts Institute of Technology. By that time he and Monique had three sons and a daughter. **An assistant professor at MIT earned an annual salary of $2,400, so money was tight. Tom heard about an opening for a staff scientist at Boeing. He and Monique flipped a coin. Boeing won, and they piled the four kids in the car and began the drive to Seattle. Tom reported to work, and Monique got a job at the University of Washington.**

It’s hard to tell if Rona ever actually used his engineering degree at Boeing, at least in the sense that he never designed a bomber or missile. Officially he was a senior scientist. Defense contractors like Boeing charge the government an extra fee beyond the basic materials and labor it takes to build a B-52 or an air-launched cruise missile. This money goes into an account for preparing bids and proposals (B&P, in defense contractor jargon), which Boeing used to pay for most of Rona’s salary.

The idea was that Rona would develop new ideas for using military hardware—hopefully, new Boeing hardware. In any case, Rona effectively had a license to look at any technology or topic that seemed interesting and was a potential market for Boeing. It was almost as good as being a professor at a major university, if not better.

People were still trying to assimilate the lessons of World War II when Rona arrived at Boeing. The war was just ten years past, and everyone was still trying to figure out the legacy of what Winston Churchill called the "wizard war"—the contest of electronic weapons and countermeasures.

The British had learned the hard way just how complex this game could be. **Electronic warfare had become a critical factor in World War II during the Battle of Britain.** In 1940 émigrés who had escaped the Continent told British intelligence that the Germans had developed some kind of "beam" weapon. At first the Brits thought this might be a ray gun that could shoot down aircraft by electronically frying their ignition systems; the refugees had talked about the Germans' testing a "beam weapon that stopped cars."

When they dug deeper into the reports, though, the Brits discovered that translators had mangled the syntax; what the émigrés really meant was that the Germans were testing a weapon that required them to stop cars-that is, stop nearby traffic to avoid radio interference. Later the British bugged the cells of some German POWs and learned that the weapon was a radio device for guiding bombers to their targets. 1

The Luftwaffe had developed a system of steerable radio beams criss-crossing Britain from stations in France and Germany. A primary beam traced a path to the target for the pilot to follow. If the pilot went off course, the beam would grow weaker, and this would trigger a buzz in his headset telling him to correct his heading. Additional beams bisected the flight path to alert the bombardier as he approached the release point. When the signal from the final crossbeam peaked, the bombardier heard a signal in his earphone and he knew he was over the target. It was like an electronic ". marks the spot."

Eventually the British learned how to deduce the direction of the beams and thus figure out which targets to protect. Yet this breakthrough had little to do with detecting the beams themselves. The real trick was in intercepting and deciphering the communications that the Luftwaffe used to tell their radio stations where to aim their beam each night. This revealed the direction and frequency of the beams, and with this information, the British could both determine the target the Germans planned to bomb, and also track a beam back to its transmitter.

The British soon learned how to transmit their own signals on the same frequency, jamming the receivers on the aircraft or causing the bombardier's signal to go off before his aircraft actually reached its target. Combined, all of these separate ingredients provided the components of an information warfare operation. The British learned where the Germans planned to attack, manipulated the Germans' view of the situation, decided how to respond, and then reacted before the Germans knew what they were up to.

The British thus had the advantage, but they then had to answer the Perennial Question of Information Warfare. Even Indian faced the Perennial Question when they first discovered a rival tribe using smoke signals. it sill confounds information warriors even today: Deny, deceive, destroy, or exploit? Do you transmit your own smoke signals to interfere with his? Do you send bogus signals to confuse your adversary so that he is easier to kill? Do you find the enemy sending the message and kill him? Or do you quietly watch the signals so you know where your adversary plans to be, head him off, and kill him then?

If the Brits jammed the beams or destroyed the radio stations, they might have eliminated the beam system temporarily. The Germans, however, would then have known that their guidance system was successful, or at least successful enough that the British believed they needed to neutralize it. Some German program manager would likely have used this fact to justify a request to build new transmitters that were better hidden and transmitted on different frequencies.

On the other hand, if the British simply sent their fighters to protect the target designated in the deciphered message, some German bombers would have gotten through. Even worse, if a squadron of Spitfires or Hurricanes regularly appeared at the appointed place night after night, the Germans would have eventually figured out that the British had cracked the cipher, which was about the most valuable secret the British had at the time.

This question of how best to attack an information system once you have the advantage—and who should do it—is an old one. Even today it is good for countless interagency meetings and memoranda. The Indian tribes probably had strategy meetings to deliberate how to deal with the smoke signal threat. One warrior likely proposed killing the signal senders, leaving their rivals blind, while another argued passionately for using the information to lay an ambush for the enemy braves who were being directed by the signals.

In the end, the British did a little of each. They jammed some of the signals some of the time, just enough to confuse the Germans. They bombed some of the radio stations. They even leaked some fanciful reports claiming that they had learned how to "bend" radio beams.

The goal was to keep the Germans off balance, and the plan worked. The Germans never lost confidence in their technology and kept using the same beam navigation system. By September 1940 the British had shot down 1,400 German aircraft. German bombing became less accurate. And Ultra, the secret intelligence based on the decrypted intercepts, remained secret until 1974, when the British government itself revealed its coup. 2

Even so, no one had really given much thought to how all these pieces—jamming, deception, intelligence—fit together. The really important thing was always the weapon-a gun or aircraft. Communications, tracking, and guidance were merely "support systems."

This was all about to change, thanks to other events underway in Seattle. As far back as 1851, when the city fathers convinced Henry Yesler to build his newfangled steam—powered sawmill along the banks of the Puget Sound, Seattle had risen, and fallen, on each new wave of technology. After Bill Boeing built his first seaplane for the Navy in 1917, the new technologies driving the Seattle economy were mainly based on aerospace—first airmail, then bombers, and more recently, missiles and satellites.

In the 1960s a new technology began to drive the Seattle economy: computers. Up to then, computers were scarce and expensive, and could only run one program at a time. **Then in 1957 a young mathematics graduate student named John McCarthy proposed a revolutionary idea: time-sharing, or having a single computer run several programs simultaneously.** This completely changed the computer business and, by extension, Seattle.

McCarthy, who was visiting MIT on a fellowship at the time, observed that the slowest part of a computer system is always the person operating it. We work at human speed; the computer works at electronic speed. The computer requires just milliseconds to run a typical calculation. McCarthy, later a distinguished professor in computer science at Stanford, realized that if you can collect computer jobs from many users, the computer can electronically rack-and-stack the jobs as they arrive, perform the operations as capacity becomes available, and thus run more or less continuously. 3

A Teletype—a typewriter that transmits a different electronic signal for each character in the alphabet—made it possible to do all this from miles away. The basic idea for the Teletype had been kicking around since 1909, but it was not until 1931 that the Bell System had introduced it into computers.

It did not take long for some early entrepreneurs to put all the pieces together and see a business opportunity. One could buy a computer, hook users into it

It did not take long for some early entrepreneurs to put all the pieces together and see a business opportunity. One could buy a computer, hook users into it with Teletypes, and sell portions of the computer's capacity to companies that couldn't afford to buy their own.

Time-sharing became popular at universities, which typically had two or three large computers located somewhere on campus, and tens of thousands of faculty and students who wanted to use them. So it was little wonder that many of the people who tried to get into the timesharing business were college staff, like Monique Rona.

By then Monique had expanded her repertoire from oceanography to computer science. Soon she found herself running the university's computer center. Tom helped with the financing and Monique got together with some university colleagues to buy a Digital PDP-10. They set up the Computer Center Corporation—C-Cubed, for short—in an office near the campus. Monique put a Teletype on the kitchen table, and they were in business.

The PDP-10 had just hit the market. Being a new machine, it was prone to electronic burps and hangfires. The C-Cubed partners thought they might cut a deal where Digital would give them a discount on the computer if they worked out the bugs.

As it happened, one of the Rona boys attended the Lakeside School, a local private academy, and had heard of some classmates who liked to work with computers. Some of the Lakeside moms had bought their kids a Teletype and a few thousand dollars of computer time from local companies with money raised from a rummage sale. The moms hoped their kids might learn a few computer skills writing programs to play ticktacktoe and the like.

The kids had other ideas. They began playing with the Teletype day and night, taking apart programs and writing some of their own. In no time they burned through the computer time their mothers had bought them and had to look for some new benefactors, just when Monique was looking for some eager minds to test her PDP-10. The boys cut a deal with C-Cubed: the boys would look for bugs in the PDP-10, and C-Cubed would give them some time on its computer.

Two of the kids, Bill Gates and Paul Allen, seemed to have a knack for computers. When the machine crashed, they would fetch the "core dump" from the trash and search through the machine language line by line to find the bug. They wangled operating manuals from the staff. Eventually the "Lakeside Programmers Group" came to know the insides of the PDP-10 about as well as C-Cubed did. So, when they ran out of their allotted time on the machine, they naturally took the simple expedient of fiddling with the computer's operating system to set back the clocks. Bill, Paul, and their Lakeside buddies Ric Weiland and Kent Evans were four of the earliest computer hackers. 4

Alas, the market for computer time-sharing never worked out as well as Monique had hoped, and C-Cubed eventually went broke, another case of roadkill on the path to IT riches. Gates and Allen went on to other ventures. **One was a new company, "Micro-Soft," which they incorporated in April 1975 to sell programs for the Altair 8800, the first personal computer.**

Meanwhile, Tom and Monique had that Teletype on their kitchen table. Computers—especially computers that talked with other computers—were part of the family. Tom could see that the Teletype in the Rona kitchen communicating with the PDP in the C-Cubed office near the university was no different than, say, a radar off the coast of New Jersey communicating with a central computer at the North American Air Defense Command in Colorado.

Rona could see that any widget that collected, moved, or processed data was part of a system, each dependent on the other. He could also see that every widget in a system was a potential point of vulnerability, as was the information that passed through them. These so-called support systems were potentially a better target than the weapon itself.

This had not occurred to anyone before, probably because information machines had never routinely talked to one another before. But what Rona now saw was clear: **Control the information flowing through your adversary's computers and communications networks, and you could control the outcome of a battle or a war. Or, as Rona's monograph, Weapons Systems and Information War , put it, "Countermeasures aimed at the external flow of information will be further improved to the point that they may well become crucial in influencing the outcome of future engagements.**—" 5

Often, in common English, this meant that the best way to defeat your enemy was to attack the components of its information systems, and Rona was broad-minded in defining "component." It included the hardware, of course, but it could just as easily be software, the people operating the system, the people getting the information out of the system, or the data that traveled through it. The best component to attack depended on the opportunities at hand and the risks one was willing to take.

In fact, Rona said, information war offers a major advantage over the old-fashioned kind. In information war, you have a menu of options—that Perennial Question of deny, deceive, destroy, or exploit? It offers an entire matrix of potential pressure points and methods for attacking the enemy. And if your target happens to figure out what you are up to, you can change tactics. The only challenge is to adapt faster than your adversary.

Boeing published Rona's monograph in the summer of 1976 as a "think piece" for company staff and customers. Tom Rona was the first person to use the term "information war" in print. Considering that the Internet was still thirteen years away and a "home computer" was something you built from a box of components with a screwdriver and a soldering gun, it was not a bad piece of prognostication.

1998 (Jan 13) - Husband passes (see Washington Post)

Source : [HN01AO][GDrive]

Thomas P. Rona, 74, a lecturer and consultant who was a former deputy director of the White House Office of Science and Technology, died of hypertensive cardiovascular disease Dec. 27 at his home in Bethesda.

Dr. Rona came to Washington at the beginning of the Reagan administration. He held several posts dealing with science policy before becoming office deputy director in 1986. He retired in 1989 and since then had been a lecturer and consultant.

His clients included the Defense Department, the Mitre Corp., the Bionetics Corp. and the Johns Hopkins University's Applied Physics Laboratory. He was the author of the 1982 book "Our Changing Geopolitical Premises" and was writing a political novel at the time of his death.

Dr. Rona, who was born in Hungary, was an electrical engineering graduate of the Ecole Polytechnique in Paris. He moved to Montreal in 1949 and then to Boston, where he served on the faculty of the Massachusetts Institute of Technology. He received a doctorate in engineering from MIT. In 1959, he joined the Boeing Co. in Seattle. He lived in Seattle until moving to the Washington area. His hobbies included painting, listening to classical music and raising tropical fish. He spoke four languages and held several technical patents.

His first wife, the former Monique R. Noel, died in 1975.

Survivors include his wife, the former Jinnett McBride, whom he married in 1987 and who lives in Fairfax; four children from his first marriage, John Michael Rona, Thomas Rona Jr. and Maree Helen Rona, all of Seattle, and John Christopher Rona of Mount Vernon, Wash.; a brother, George, of Brussels; and seven grandchildren. Biography[edit]

Ross was born in San Francisco and grew up in Belvedere, California.[2] His Jewish mother and Catholic stepfather raised him in a non-religious atmosphere.[3] Ross graduated from University of California, Los Angeles in 1970 and did graduate work there, writing a doctoral dissertation on Soviet decision-making.[4] He became religiously Jewish after the Six-Day War.[3] In 2002, he co-founded the Kol Shalom synagogue in Rockville, Maryland.[3]

Career[edit]

1970s–1993[edit]

During President Jimmy Carter's administration, Ross worked under Deputy Assistant Secretary of Defense Paul Wolfowitz in the Pentagon. There he co-authored a study recommending greater U.S. intervention in the Persian Gulf region "because of our need for Persian Gulf oil and because events in the Persian Gulf affect the Arab–Israeli conflict."[5]During the Reagan administration, Ross served as director of Near East and South Asian affairs in the National Security Council and Deputy Director of the Pentagon's Office of Net Assessment (1982–84).[4]

Ross returned briefly to academia in the 1980s, serving as executive director of the Berkeley-Stanford program on Soviet international behavior from 1984–1986.[4]

In the administration of President George H. W. Bush, Ross was director of the United States State Department's Policy Planning Staff, working on U.S. policy toward the former Soviet Union, the reunification of Germany and its integration into NATO, arms control, and the 1991 Gulf War.[4] He also worked with Secretary of State James Baker on convincing Arab and Israeli leaders to attend the 1991 Middle East peace conference in Madrid, Spain.[3]

Middle East envoy[edit]

Ross (right) with Ehud Barak in 1999.

Although Ross had worked for outgoing Republican President Bush (even assisting in his re-election effort), incoming Democratic Secretary of State Warren Christopher asked Ross to stay on for a short time to help with early Middle Eastern policy in the new administration.[6] In the summer of 1993 President Bill Clinton named Ross Middle East envoy. He helped the Israelis and Palestiniansreach the 1995 Interim Agreement on the West Bank and the Gaza Strip and brokered the Protocol Concerning the Redeployment in Hebron in 1997. He facilitated the Israel–Jordan peace treaty and also worked on talks between Israel and Syria.[4]

Ross headed a team of several people in the Office of the Special Middle East Coordinator, including his deputy Aaron David Miller, Robert Malley, Jon Schwarz, Gamal Helal, and Daniel Kurtzer (until 1994). Ross, consulting his team, drew up the Clinton Parameters as a bridging solution to save the Israeli–Palestinian negotiations in December 2000.[7]

Ross was criticized by people on both sides of the conflict. Former Palestinian Foreign Minister Nabil Shaath described him as being more "pro-Israeli than the Israelis."[8] Occasional references to his Jewish ancestry were brought up within the Arab world (although Ross maintains this was not a problem with other heads of state during negotiations), while some conservative Israelis branded him "self-hating"—each questioning his ability to be unbiased,[9][10] though Palestinians involved in the negotiation process would insist that his perceived lack of objectivity had little to do with his religion.[11] Describing Ross, Roger Cohen wrote that "Balance is something this meticulous diplomat [Ross] prizes. But a recurrent issue with Ross, who embraced the Jewish faith after being raised in a non-religious home by a Jewish mother and Catholic stepfather, has been asked whether he is too close to the American Jewish community and Israel to be an honest broker with Iran or Arabs. Aaron David Miller, after years of working with Ross, concluded in a book that he 'had an inherent tendency to see the world of Arab–Israeli politics first from Israel's vantage point rather than that of the Palestinians.' Another former senior State Department official, who requested anonymity ... told me, "Ross's bad habit is pre-consultation with the Israelis."[12]

Post–Clinton-era activities[edit]

After leaving his position as envoy, Ross returned to the Washington Institute for Near East Policy as counselor and Ziegler Distinguished Fellow. He became chair of the Jerusalem-based think tank, the Jewish People Policy Planning Institute, funded and founded by the Jewish Agency in 2002.[13]

During these years he taught classes at Marquette University, Brandeis University, Georgetown University and the Kennedy School of Government at Harvard University."[3] He also wrote frequently for publications like *The Washington Post*, *The New York Times*, *The Jerusalem Post*, *The New Republic*, *USA Today*, and *The Wall Street Journal* and worked as a foreign affairs analyst for the Fox News channel.[14]

Ross was a noted supporter of the Iraq war and he signed two Project for a New American Century (PNAC) letters in support of the war in March 2003.[15] However, he opposed some of the Bush Administration's policies for post-war reconstruction.[16] He also opposed Bush's policy of avoiding direct talks with Iran.[3]

Obama Administration positions[edit]

According to *The Wall Street Journal*, Ross, along with James Steinberg and Daniel Kurtzer, were among the principal authors of then-presidential candidate Barack Obama's address on the Middle East to AIPAC in June 2008.[17] It was viewed as the Democratic nominee's most expansive on international affairs.[18]

Ross was appointed Special Advisor for the Persian Gulf and Southwest Asia to Secretary of State Hillary Clinton on February 23, 2009.[19] On June 25, 2009 the White House announced that Ross was leaving the State Department to join the National Security Council staff as a Special Assistant to the President and Senior Director for the Central Region, with overall responsibility for the region. The Central Region includes the Middle East, the Persian Gulf, Afghanistan, Pakistan and South Asia.[20]

Haaretz reported that Ross's work as a Middle East aide in the Obama administration was burdened by tension with special envoy George Mitchell, to the point that Ross and Mitchell sometimes refused to speak to each other. This report indicated that the tension was caused, at least in part, by Ross's occasional efforts to conduct negotiations with Israeli government officials without notifying Mitchell. For example, in both September and November 2010, Ross was said to have tried to persuade Prime Minister Benjamin Netanyahu to freeze settlement construction during negotiations with the Palestinian National Authority, in exchange for unspecified private assurances and a major military arms transfer from the United States.[21]

Palestinian officials reportedly viewed Ross as beholden to the Israeli government, and not as an honest broker or even-handed facilitator of negotiations. For a significant period, Ross refrained from meeting Palestinian Authority officials, while continuing to hold talks with Israeli officials during his visits to the region.[21]

On November 10, 2011, Ross stepped down from his post in the Obama administration.[22] He rejoined The Washington Institute as William Davidson Distinguished Fellow, Counselor, Irwin Levy Family Program on the U.S.-Israel Strategic Relationship. He currently serves on the advisory board for the non-profit America Abroad Media.[23] In 2006, he taught at Georgetown University's Walsh School of Foreign Service as a Distinguished Professor in the Practice of Diplomacy.[24]

Controversies[edit]

See also: Positions on Jerusalem

In their 2006 paper *The Israel Lobby and U.S. Foreign Policy*, John Mearsheimer, political science professor at the University of Chicago, and Stephen Walt, academic dean of the Kennedy School of Government at Harvard University, named Ross as a member of the "Israeli lobby" in the United States.[25] Ross in turn criticized the academics behind the paper.[25] In 2008, *Time* reported that a former colleague of Ross, former ambassador Daniel Kurtzer published a think-tank monograph containing anonymous complaints from Arab and American negotiators saying Ross was seen as biased towards Israel and not "an honest broker".[16]

Ross's memoir of his experiences, *The Missing Peace: The Inside Story of the Fight for Middle East Peace* tells his side of the story and outlines the key lessons to be drawn.[26][27]His 2007 book, *Statecraft: And How to Restore America's Standing in the World*, criticizes the administration of President George W. Bush for its failure to use the tools of statecraft to advance U.S. national interests. He advocates instead for a neoliberal foreign policy which relies on a much broader and more effective use of statecraft.[28] While having worked under both Republican and Democratic administrations, Ross himself is a Democrat.[29]

Ross states in *The Missing Peace* that he and other American negotiators pushed Israeli Prime Minister Ehud Barak to accept Palestinian sovereignty over Arab neighborhoods of East Jerusalem during the Middle East Peace Summit at Camp David.[30] Ross wrote part of Barack Obama's speech to the American Israel Public Affairs Committee during the 2008 Presidential campaign, and the speech stated that "Jerusalem is Israel's capital" and that it should not be divided again. *The Jerusalem Post* reported in November 2008 that, according to Ross, these were "facts." However, Ross stated that the "third point," which is the position of the United States since the Camp David Accords, is that the final status of the city will be resolved by negotiations.[31]

In February 2018, he penned an opinion piece in the Washington Post strongly supportive of the Saudi crown prince Muhammad bin Salman, calling him "a Saudi revolutionary" and stating that he saw "him as more like Mustafa Kemal Atatürk—a leader who revolutionized Turkey by taking away the power of the religious base and secularizing the country."[32]

Affiliations[edit]

Ross co-founded the advocacy group United Against Nuclear Iran (UANI) with Ambassador Richard Holbrooke, former CIA director R. James Woolsey Jr., and former U.S. ambassador to the United Nations for Management and Reform Mark Wallace.[33] He is currently on the advisory board of UANI as well as the Counter Extremism Project.[34][35]

Henry Rothschild (born 1920)

[aa6][GDrive]

This page of notes is for **Henry Rothschild**, born in 1920. His name is of interest as he was a senior member of **Philipp Brothers Incorporated** (where he was a mentor to **Marc Rich**), both before and after its acquisition by **Engelhard Corporation** . Naturally, any person with the last name of **Rothschild** is of interest.

It is extremely difficult to locate data on this **Henry Rothschild (born 1920)** . This page, while not well organized, is probably the most comprehensive source available.

It is believed (since it has been stated in reference books) that **Henry Rothschild (born 1920)** is not directly related to the **Rothschild** family that has made its fortune in banking, but this is being validated.

https://www.legacy.com/obituaries/nytimes/obituary.aspx?n=henry-rothschild&pid=157928976

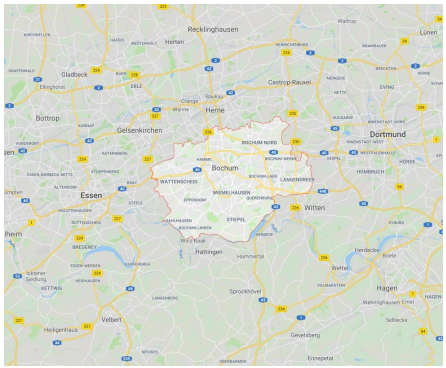
ROTHSCHILD--Henry, passed away June 2 at age 92. Beloved husband of the late Gertrude Neumark Rothschild.

Published in The New York Times on June 4, 2012

conclusion - Born 1920

1920 - Born in Germany

Henry Rothschild was born in **1920**.in "***Bochum, Germany***" [aa5][GDrive] . For more on Bochum, Germany : See https://en.wikipedia.org/wiki/Bochum



1930

Henry Rothschild began learning (and working) at a very young age. *"[Henry] Rothschild had become a lehrling in **Cologne, Germany**, at the age of ten [..]."* [aa1][GDrive]

1936 - Apprenticeship to the Lissauer firm in Cologne, Germany

"[Henry] Rothschild was also apprenticed rather early, at age sixteen, to the Lissauer firm in Cologne." [aa5][GDrive] .

" As we already saw in the cases of Salo Floersheim, Ullmann and Jesselson, an apprenticeship in Germany was no light matter. It usually gave the young man a thorough training in the basics of commercial matters, plus a good knowledge of the specialties of the firm. In the case of Lissauer, it was ore business, and also residues, scrap and metals, as well as chemicals."

1939 - Junior employee of Hoschild, in Bolivia

*"[**Henry Rothschild** was,] in 1939 a junior employee of **Hochschild**, a fresh import from Europe and quite unknown to the Bolivian authorities. He was in a word, rather expendable, andt he Hochschild firm used him to take food, blankets and clothing to the imprisoned men."* [aa5][GDrive] . Henry Rothschild would have been 19 years old at this time.

1969 - Senior Vice President of Engelhard Minerals and Chemicals Corporation

See [aa12][GDrive] . Read more about **Engelhard Corportation** .

page 37

Baja - or Lower - California is a Mexican state that is separated from the mainland by the Gulf of California. It is rugged, difficult country. There, south of the town of Santa Rosalia, a rancher one day found colourful nodules that turned out to be copper ore. The find eventually came to be identified as three bodies of rather complex ores. The grade of the first outcroppings was ranging 20-25"o copper. Work began in 1872. The ore was handpicked and lightered on to ships that sailed for Europe.

in 1885, the Mexican govemment granted a concession to exploit the find to a French group controlled by the Rothschilds which set up the Compagnie du Bole-o. They opened the mine, and built a smelter, a port, a power plant and even a 45 kilometre railroad. By 1894, El Boleo produced about 10000 tonnes of copper matte and black copper per year. In 1924, the smelter was rebuilt and the product was thereafter known as blister copper.

The operation was highly suecessful and profitable for the shareholders in the early years. But by the 19305, costs had risen, prices and grades had declined, and 1-21 Boleo's useful life seemed over. But the demand for copper during World War 11 and eventually tax concessions and then subsidies kept the operation going until quite recently.

... page 135 ---

Henry Rothschild*, of Hartsdale, New York, cleared up many questions I had about the Mina Matilde story. Mr Rothschild was one of the senior executives of Philipp Brothers involved in the story.*

page 239

The end of the war thus found the Guggenheims vastly richer and more powerful than at its outbreak; but also with a somewhat tarnished reputation - for profiteering and poor labour relations. They were probably also by then the second richest - next to be Rothschilds - Jewish family in the world."

Henry Rothschild was an example of a key personnel member who was *"eagerly recruited"* by "***Philipp Brothers***" from "***Hochschild***". [See https://www.immigrantentrepreneurship.org/entry.php?rec=167#_edn25 }:

"Several of the new traders were recruited away from Moritz Hochschild's organization. Hochschild, born and raised in Germany and related to the owners of Metallgesellschaft, had from the 1920s onwards become one of the dominant figures in the Bolivian tin trade. Known as one of the three Bolivian "tin barons," he controlled about 25 percent of all Bolivian tin mines.[24] To run his business organization, he hired mainly German Jews, several of whom had prior experience with German metal trading companies. Yet Hochschild found it increasingly difficult to operate in Bolivia in the 1940s and early 1950s. After the disastrous Chaco War of 1932-1935, Bolivian political life became increasingly volatile and the country experienced revolts, coups, and civil wars. In the process, Hochschild's company experienced several setbacks. The situation culminated when a new Bolivian government nationalized all of Hochschild's mining assets in 1952. Philipp Brothers eagerly recruited key personnel like Adolfo Blum and Henry Rothschild from Hochschild.[25]"

[25] The account of Hochschild and his organization is mainly based on Helmut Waszkis, Dr. Moritz (Don Mauricio) Hochschild 1881-1965: The Man and His Companies. A German Jewish Mining Entrepreneur in South America (Madrid: Iberoamericana, 2001).

From "Metal Men: Marc Rich and the $10 Billion Scam"

See [aa1][GDrive])

Nowhere did the company's kitchen-table style of business prove itself better than Bolivia, where Philipp Brothers remains the major conduit for the troubled Andean nation's outpouring of tin, tungsten, and antimony. The association between Philipp Brothers and Bolivia began in 1927, when Arturo Gruenebaum opened the company's first La Paz office, and has transcended the 356 assorted coups, elections, military upheavals, and states of emergency that have rocked the country ever since. ***One of the men who went there was Henry Rothschild, whom Philipp Brothers had lured away from Associated Metals in 1946****. By the time Rothschild had arrived at Philipp Brothers, Jesselson had become the firm's top trade negotiator.* ***Rothschild, who would eventually run the trading arm of Philipp Brothers*** *alongside Jesselson, quick- ly assumed the role of troubleshooter. "I got the fireworks and Jes lit the fuse," Rothschild says. "We were the perfect team."* ***Rothschild was no simple high- road executive who traveled the world just to negotiate for minerals. He was the personification of the Philipp Brothers trader. Rothschild crawled down into Bolivian mines, picked away at veins of tungsten ore alongside coca leaf- chewing miners, and had the bejesus scared out of him on more than one occasion when the decomposed corpses of five-hundred-year-old Indian min- ers fell out of ancient underground holes and buried him in pitch black tun- nels three hundred feet beneath the Altiplano****. Such feats, however, were part of the job description for all Philipp Brothers traders.*

...

Philipp Brothers, the largest raw-material trading company in the world, was scouring American universities for young men they could snatch and mold into lehrlings —the Yiddish word used to describe young men apprentic- ing to be traders. The man in charge of the program was Henry Rothschild, who, like everyone else at Philipp Brothers, had escaped the Nazi holocaust.

...

Rothschild had become a lehrling in Cologne, Germany, at the age of ten and had no problem encouraging Rich to sacrifice a college education to become a trader at Philipp Brothers*. The company, in fact, preferred to edu- cate their people in-house, the traditional European approach and the Philipp Brothers' way of doing business. Lehrlings were trained to trade every com- modity known to man. The company was run like a large family. Department heads such as Rothschild acted like stern fathers, not executive vice presi- dents. And in Marc Rich, Rothschild sensed something special.*

*1

In this will construction proceeding, the respondent, Susan Nieschlag, a cousin of the decedent's predeceased spouse, moves, pursuant to CPLR 3212, for summary judgment and an order determining that the decedent's collections of stamps, platinum, gold and silver coins and various currencies ("the collections") constitute tangible personal property specifically bequeathed to her under Article TWO (A) of the decedent's will dated March 22, 2010. The motion is opposed by the executor, who contends that the collections are part of the residuary estate that passes to an irrevocable trust established by the decedent with numerous beneficiaries, principally charities ("the trust"). The executor is the trustee. Pursuant to a stipulation of the parties, a SCPA 2103 proceeding commenced by the executor against Nieschlag seeking turnover and inspection of stamps allegedly gifted to her by the decedent's spouse is being held in abeyance until determination of this motion. A summary judgment motion by the executor in an underlying will construction proceeding was denied (see Matter of Rothschild, NYLJ, Mar. 18, 2014, at 23, col 1 [Sur Ct, Bronx County 2014]).

The decedent died on June 2, 2012, and his spouse, Gertrude F. Rothschild, predeceased him on November 11, 2010. They fled Germany during the 1930's to escape the Holocaust, married in 1950 and had no children. The decedent was a successful commodities trader, and his spouse was a scientist and professor at Columbia University. They executed similar trusts and wills on March 22, 2010. The executor is the fiduciary of the spouse's estate and a co-trustee of her trust. Although the decedent's will was admitted to probate by this court, the will of the decedent's spouse was admitted to probate by the Surrogate's Court, Westchester County. The decedent's will and trust leave approximately 70 percent of the net distributable estate to charities, and the remaining 30 percent remains in trust for designated individuals with the balance passing to charities upon their deaths. It is uncontroverted that the decedent and the spouse did not sell any of the stamps, coins, bullion or currency. Their collections were not maintained in the traditional way or displayed in their various homes but were secreted in various locations in their Hartsdale, New York house. Article TWO (A) of the decedent's will provides that:

"I give all of my tangible personal property (other than currency) including without limitation, wearing apparel, personal effects, jewelry,

....

Nieschlag replies that although the executor refers to the Nieschlags as "distant relatives" they are the only family that the spouse had, both the decedent and the spouse named Nieschlag as a fiduciary in prior wills, and she provides affidavits from her husband and daughter concerning their close relationship with the decedent and spouse, who gave them substantial gifts. Nieschlag concludes that the decedent and the spouse intended that she and her family receive the collections, whether through inter vivos gifts or by virtue of their bequest to Nieschlag of "tangible personal property excluding currency, without limitation."

Case Digest Summary

ESTATE OF HENRY ROTHSCHILD, Deceased (12/1424/D) — In this contested proceeding to terminate a trust commenced by the petitioner, the executor of the estates of the decedent and his spouse and also trustee of various trusts established and/or funded by them, the parties filed a written stipulation discontinuing the proceeding without prejudice or costs.

Full Case Digest Text

ESTATE OF HENRY ROTHSCHILD, Deceased (12/1424/D) — In this contested proceeding to terminate a trust commenced by the petitioner, the executor of the estates of the decedent and his spouse and also trustee of various trusts established and/or funded by them, the parties filed a written stipulation discontinuing the proceeding without prejudice or costs.

Accordingly, this decision constitutes the order of the court marking the proceeding "discontinued" pursuant to the parties' written stipulation and subject to renewal upon two weeks' written notice to the parties and the court. Proceed accordingly.

Sensitive Assignments:

When Rich joined the company in 1954, Philipp Brothers still essentially consisted of a tightly knit group of German-Jewish immigrants. The names of the major players who were active in the company provided an indication of their heritage: ***Ludwig Jesselson***, ***Adolfo Blum***, *and* ***Henry Rothschild****. They were all pioneers of economic globalization who helped write trading history. These men became mentors to Rich, whose family was known in trading circles and whose father came from the tragedy that was Germany—just as they did. He had the best teachers in the business. Most important, Rich had the strength of will and the patience to listen, observe, and learn.*

So Rich learned how to become a commodities trader from the ground up. After two years he became a junior trader, and ***Henry Rothschild*** *soon took him under his wing.* ***Rothschild, who was not a member of the banking family, was born in Bochum, Germany****, entered the commodities business when he was sixteen,* ***and [Henry Rothschild] had previously done business with Marc Rich's father****. He is described as a shy, taciturn, and quick-thinking analyst. The master and apprentice were kindred spirits when it came to their similar ways of thinking.*

[Henry] Rothschild *was an extremely demanding boss who was responsible for the South American market at* ***Philipp Brothers*** *and for developing the firm's expanding network in Europe. He increasingly delegated the day-to-day business to Rich, who effectively became his assistant. "I was fascinated by the size of the market," explains Rich. "Take oil or aluminum. You can find those materials in almost any product you touch. The whole world needs them, from east to west and north to south." It was a fascination that would remain. The first commodity he personally traded was Bolivian tin.*

[...]

[Marc] Rich *was now the man to see when it came to* ***mercury****. It was his first business coup, and it earned significant profits for* ***Philipp Brothers****. The young dealer had not been at Philipp Brothers very long, yet this success strengthened his position enormously within the company. It was proof to his superiors that he had the talent to spot opportunities, the courage to grasp them, the patience to successfully conclude a deal, and enough common sense to avoid excessive risks.*

When the manager of the Bolivian office of Philipp Brothers had to travel back to England because his mother was having an operation, it was immediately clear who would replace him. ***Henry Rothschild*** *sent* ***[Marc] Rich*** *for six months to the same South American country where* ***David Rich*** *had also done business. Bolivia was a dangerous place known for its political and economic instability. A nationalistic movement had brought about a revolution in 1952, and the country's large mines had subsequently been nationalized. The South American country has been an important source of silver, tin, and tungsten since the sixteenth century. Rich not only learned perfect Spanish in La Paz, Bolivia, he also picked up the essentials of doing business in politically volatile countries. He was evidently very adept in his dealings. A partner at the time relates how he always kept the risks under control und managed to establish good contacts thanks to his quiet, modest style.*

Following his success in Bolivia, Philipp Brothers sent its rising star to South Africa for the first time in 1958. At that point the country was still in the Commonwealth, and the trade boycott against the apartheid regime had not yet begun. It was a journey to his first defeat. Rich thrashed out the details of the sale of a manganese ore mine for months on end, and he remembers the negotiations as being "very tedious, very long." In the end, after six months of negotiating, "I couldn't conclude the purchase. I had to come home with empty hands." He did not hear a single word of criticism from his mentors ***Rothschild*** *and* ***Jesselson****. They both knew that Rich would profit from the experience.*

Despite this single setback, he had clearly demonstrated his capacity for sensitive assignments. He had proved that he could stay calm in chaotic situations. He was persistent and innovative without ever becoming foolhardy. More than anything else, he was enterprising and resourceful. Those were exactly the qualities that Philipp Brothers was counting on in early 1959. A bearded revolutionary was in the process of rewriting history in Cuba. Philipp Brothers, which had enjoyed close business ties with the Batista regime, was not amused. It needed a troubleshooter.

page 93

The Hirsch-owned firm in Amsterdam, NV Groma, now became Jesselson's employer. Many German Jewish firms were moving to Holland to continue their business from there. Julius Philipp had done so. as had the Lissauer firm from Cologne. Dr. Menno Liss-auer himself, and his son-in-law, Walter Rothschild, moved to New York to manage their US firm, Associated Metals.4

{{{ Lissauer - I think that is where Marc Rich worked? }}}

96-97

Back in Bolivia, in June of 1939 President Busch had brought about major changes in the business. He had signed a decree that the Banco Minero would henceforth have a monopoly to buy the production of the small mines, and that all foreign currency proceedS from the exports of mining products be delivered to the government. This was the effective end of the rescate business

which Hochschild, Duncan Fox and Philipp Brothers, as well as others, had worked for years to set up. Admittedly, the business had been profitable, but at the same time, the loans, advances and supplies that the ore buyers had made available to the miners had constructively contributed to the development of dozens of mines. And now, the business was terminated overnight. The ore buyers decided not to accept this, and a letter was soon circulating, signed by Dr. Mauricio Hochschild and Adolfo Blum on behalf of the Hochschild group, Arturo Gruenebaum on behalf of Philipp Brothers aswell asby Duncan Fox, recommendingto the miners to protest the decree. Busch took this asan affront and aseconomic sabotage, and he ordered the principal ore buyers imprisoned. He was determined to punish them in an exemplary way, especially Dr. Hochschild who was to be shot. The others were to stay in jail for a number of years. A cabinet session that was to decide the fate of the prisonerssplit evenly on the issue and it took long discussions before Busch could finally be dissuaded from taking draconian measures. After a few weeks they were all pardoned; Busch com-mitted suicide in August; andthe matter was eventually forgotten, except for the decree which remainedin force.

This is the first time that we meet Henry Rothschild. He was in 1939 a junior employee of Hochschild,a fresh import from Europe and quite unknown to the Bolivian authorities. He was in a word, rather expendable, andthe Hochschild firm used him to take food, blankets and clothing to the imprisoned men.

Gruenebaum at once closed the Potosi office. The Oruro office also ceased buying from the small miners but it continued to buy from the medium-sized ones. The firm now decided to move to La Paz which quickly became the main office of Philipp Brothers in Bolivia. Gruenebaum ran the head office, and Max Goldschmidt took care of Oruro. In La Paz they now began to buy from Banco Minero and, eventually, also from Comibol, the Corporagion Minera deBolivia, which after Bolivia's expropriationof the big tin mines of Patino, Aramayo and Hochschildin 1952, was to become the main operator of these mines.

102-103

HENRY ROTHSCHILD

It was early in 1946 that Gruenebaum left Bolivia for New York. Soon he needed an assistant, and the right man seemed to be available.

Henry Rothschild was just twenty-six when he arrived in New York and visited Gruenebaum. They had met before, in Bolivia, when Rothschild had brought food and blankets to the prison where Gruenebaum shared a cell with Hochschild and Blum.

HERE>>>>

Born in 1920 in Bochum, Germany, Rothschild was also apprenticed rather early, at age sixteen, to the Lissauer firm in Cologne.

As we already saw in the cases of Salo Floersheim, Ullmann and Jesselson, an apprenticeship in Germany was no light matter. It usually gave the young man a thorough training in the basics of commercial matters, plus a good knowledge of the specialties of the firm. In the case of Lissauer,it was ore business, and also resi-dues, scrap and metals, as well aschemicals.

In Bolivia, Hochschild had let him begin in the accounting department in La Paz, but he was soon transferred to Potosi where he spent the next six years in different positions in the sampling area, in a mill, in underground mine workings and in the adminis-trative office. When he left Bolivia after the war, he was probably one of the most experienced managers of medium sized mines.

But six years in Bolivia had been enough. The war was over and v of 1946 he traveled to the United States and th - _ Lrossea the country by laus for three months, "to get to kentbwrfiise lan When he d13131"? fofr 2} 10th the uniqueness of his back-ground and the use u ness 0 1115 experience to the growing Philipp "Brothers organization, must have struck Gruenebaum and the oth€f5~ Nevertheless, it still took them a week to make up their minds; Philipp Brothers gained and Hochschild lost. When Hochs-child learned that Rothschild had left, he tried everything hecould to rehire him, even offering the managership in Arequipa, Peru, and Sao Paulo, Brazrl. But Rothschild had decion Philipp

It was not only Rothschild's background and training that proved very valuable to Philipp Brothers but also, as time was to show, his peculiar kind of mind. Gifted with acuttingintelligence and a light-ning fast intellect,hewas again and again to surprise associates and outsiders alike With his ability to analyze, absorb and digest a sub-

'ect, before others had even begun to understand what it was all about. His memory was phenomenal and no doubt contributed to his analytical powers. On the other hand, he was also shy and reti-cent, and thus not the most ideal person for outside contacts, which in turn was very much Jesselson's strength.

Years later, after Ullmann's death, and when Jesselson began to miss the analytical powers of his original mentor, he was to turn more and more to Henry Rothschild, and the two came to form over the years what several associates were to call "a remarkable team." Jesselson, who always bubbled over with ideas, was to find in Rothschild the ideal partner who could put the right accents on his ideas, provide the technical foundations for many a new busi-ness, and play "devil's advocate." He was also to become, among the inner circle of the group to lead the firm in the 19605 and 19705 the one who had the most knowledge and understanding of legal matters.

118

Already in 1944, Adolfo Blum hadjoined. His story will be told in chapter 8. In 1946, aswe saw, Henry Rothschild was hired and became Gruenebaum's assistant, at first doing traffic work, then writing and then supervising the 5hipping and the invoicing paper-work for the Bolivian business. But beginning in 1948, he also

began to travel, and he took on more and more management func-tions, such as supervising the organization of the foreign offices, hiring, and looking after the many intricate legal and administrat-ive details. Once Adolfo Blum began to organize the group in EurOpe, Rothschild became the indispensable link in New York who kept control and supervision over what already in the early

19505 was quickly becoming a sprawling world-wide organization. One Ben-Ami joined, a former member of the Irgun, and Jules Chender. The latter, born in Moskau in 1920, and originally called Yuli Chenderoff, had behind him a colorful career in France when he arrived in the US in 1941. He began to work in a factory as machinist, spoke at first little English but nevertheless went to nightschool at N Y U , considered himself a man of intellect, thought business would be his last choice and really wanted to become a journalist. But beside everything else, he was rabidly in favor of Israel. In the 19405, when the Zionists were struggling to get supplies into Palestine, Chender, familiar with the machine tool industry and the factories and warehouses and shipping agents that dealt with such equipment, was instrumental in arranging for the

urchase and shipment to Palestine of arms and arms-making machinery hidden in huge transformer cases. A few years later, in

1954, Chender joined Philipp Brothers and became one of the

film's foremost copper traders. He died in 1973 at age fifty-three.

Assorted -

http://www.bollyn.com/who-destroyed-the-911-evidence/

In September, when I began my research into the Zionist network behind the destruction of the steel, I called the Hugo Neu company, which was one of the two New Jersey scrapyards that "recycled" the steel. Hugo Neu was a German Jewish immigrant from Fürth (like Henry Kissinger, another Rothschild agent) who came to America and worked as a bank clerk with Seligman & Co. before becoming the head of Associated Metals and Minerals Corporation (AMMC) in New York in the 1930s with his German Jewish fellows, Meno Lissauer and Walter M. Rothschild, the company's president. Lissauer's wife, Meta, was also Walter Rothschild's sister. Hugo Neu started his own scrap metal company in 1945. The company is now run by his son, John, and has very close business ties to the state of Israel and is invested in a Mossad-linked Israeli venture fund.

https://archive.org/stream/kurtereinsbergf001/kurtereinsbergf001_djvu.txt

volunteer at an Amsterdam firm doing business between Holland and the Dutch East
Indies (now Indonesia), I landed a job at M Lissauer & Co, in Cologne, Germany. This
firm, founded in 1905 by Meno Lissauer and his brother, was a major worldwide trader in
metals, minerals and chemical products. The attraction for me was that the firm had a
offices throughout Europe as well as in New York. The latter was called Associated
Metals & Minerals Corp founded in 1924. The shares of Associated Metals were in the
name of Walter Rothschild, Meno Lissauer's brother in law, who was an American
citizen At M Lissauer & Co, Cologne I worked in the ore department for 2 years, until I
was granted the U.S. Immigration Visa. Within a week after arriving in New York in April
1937 I was hired at Associated Metals & Minerals Corp. The Lissauer group had a major
long term contract for the purchase of zinc concentrates with Howe Sound Corporation,
American company, operating a large zinc-lead mine and a lead smelter in the state of
Zacatecas in northern Mexico. It also had several purchase contracts for zinc ores and
concentrates with small Mexican owned mines The concentrates were shipped to zinc
smelters located in Belgium, France and Poland.
My initial travels to Mexico were in relation to the logistics of moving these
concentrates by rail to the port of Tampico and to negotiate for the purchase of
additional quantities of minerals and concentrates from Mexican mines.

Hugo Neu was a Jewish immigrant from Cologne who headed Associated Metals and Minerals Corp. (AMMC) in New York with two other German Jewish immigrants, Dr. Meno Lissauer and his brother-in-law, Walter M. Rothschild."

Dr. Meno Lissauer, Industrialist, Dead; Board Chairman of Associated Metals

Dr. Meno Lissauer, chairman of the Associated Metals and Minerals Corporation, 75 West Street, died yesterday at his home at 4503 Fieldston Road, Riverdale, the Bronx, after a brief illness. His age was 78.

Dr. Lissauer, who was born in Luebeck, Germany, was the chief factor in developing the company from a small beginning in 1903 in Cologne, Germany, to its present international scope. He founded the concern with $300 borrowed from a friend. In 1907 he brought his brother, the late Henry Lissauer, into the company and named it M. Lissauer & Cie. After World War I, the company helped to distribute Germany's stockpile of metallic ores and scrap.

Dr. Lissauer organized the West German Metal Dealers Association and was its president for thirteen years. He was also a delegate to the General Association of Commerce and Industry of Germany. For his assistance to the Aachen Technical College in its experiments in extracting metals from residues and wastes he received an honorary doctorate.

When the Nazis came into power in the Nineteen Thirties they put the financial pinch on the company. In 1937 Dr. Lissauer moved to the Netherlands. After the conquest of that country by Germany he fled to Lisbon and finally reached this country. Associated Metals and Minerals already existed here, as did some affiliates elsewhere. From them grew the present international organization.

Dr. Meno Lissauer

In this country Dr. Lissauer was active in philanthropy, as he had been abroad. He was honorary chairman of the metals and mining division of the United Jewish Appeal and a director of the American Federation of Jews in Central Europe. Last year he established at Brandeis University the Meno Lissauer Scholarship Endowment Fund.

Surviving are his widow, Meta; a son, Franz A. of New York; a daughter, Mrs. Hannah Hirschfeld of Scarsdale, N. Y.; a brother, Jonny of Zurich, Switzerland, and four grandchildren.

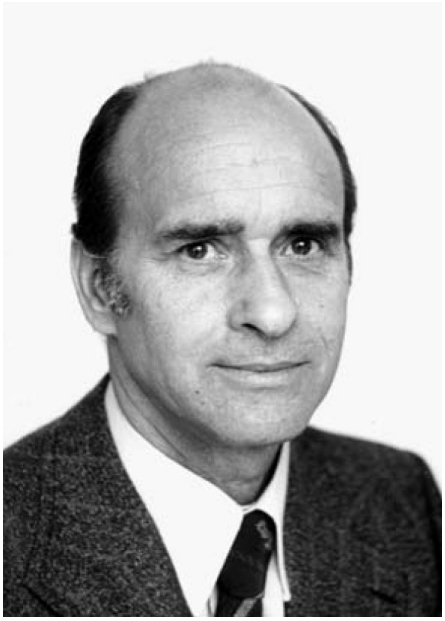
ARCHIVED NOTES : There is a separate page called henry-rothschild-b1920-notes .

Rudolf Rott (born 1926)



[HP0052][GDrive]

Wikipedia (DE) Rudolf Rott

Born - May 23, 1926 [HK005F][GDrive]

Saved Wikipedia (Feb 27, 2021) - Rudolf Rott (DE)

Source : [HK005F][GDrive]

Rudolf Rott (born May 23, 1926 in Stuttgart, † April 28, 2003 in Gießen) was a German virologist.

Rott was the son of a civil engineer and went to school in Ellwangen and Rottweil. After two years of military service in World War II, imprisonment and two years in agriculture, he studied veterinary medicine at the University of Giessen, initially from 1950, with his doctorate in 1955 on swine influenza under Elmar Roots. He then worked as an assistant at the Giessen Institute for Animal Disease Studies at Roots and in 1958 went to [Dr. Heinrich Werner Schäfer (born 1912)] at the Max Planck Institute for Virus Research in Tübingen, where he dealt with the avian influenza virus, which is also one of the flu viruses. In 1964 he became a professor in Gießen (after his habilitation in 1963) and head of the newly founded Institute for Virology, which was the first in Germany. In 1994 he retired.

Rott published over 300 scientific papers. He dealt in particular with flu viruses, for example the gene structure and genetic relationship [1] of the flu viruses and surface proteins of the flu viruses (such as neuraminidase). In the mid-1970s, he and his group were able to demonstrate the structure of the virus RNA from eight segments that could be freely exchanged, which explains the high variability of the viruses [2]. The studies at that time also showed that the pathogenicity of the viruses depended on many factors. [3] He and his group in Gießen also researched the glycoproteins of the virus envelope and their role in penetrating the host cell. They were able to prove that the cleavage of the hemagglutinin in the virus envelope by the host's own enzymes was an important mechanism for the virus to be infectious [4]. Rott and his group also demonstrated that the increase in this proteolytic activity on hemagglutinin by bacteria could contribute to the pathogenicity of the influenza viruses [5]. He demonstrated the proteolytic activation of surface glycoproteins in other viruses (such as Paramyxoviridae in Newcastle disease [6], Sendai virus infection).

He also studied the Bornash disease virus, which causes chronic brain disease in horses. [7] Rott and colleagues also demonstrated virulence in humans.

He received the Robert Koch Prize in 1987 and the Otto Warburg Medal in 1982. In 1991 he received the Max Planck Research Award. He was an honorary member of the Society for Virology (1999) and an honorary doctorate from the Free University of Berlin. He was a member of the Royal Society of Medicine (1963), the New York Academy of Sciences (1966) and the Leopoldina (1973), whose Cothenius Medal he received in 1999. In 1995/96 he was a fellow at the Wissenschaftskolleg zu Berlin.

Rott was married to Renate Kröll since 1956 and has a daughter Sabine, who is married to the former director of the Bernhard Nocht Institute Bernhard Fleischer.

Where do new virus infections come from that attract the attention of the public and the scientific community with ever increasing intensity? What role do animals play as reservoirs of these viruses? What are the mechanisms of adaptation when a virus crosses the species barrier between animals and man? Why do infections cause disease in one host species, but not in another? Fundamental contributions to a better understanding of these problems were made by Rudolf Rott who died on April 28. He was 76 years old.

Born in 1926, Rudi belonged to the generation whose youth was traumatically marked by the second World War and the post-war period. He left high school in 1943 to join the German army as a volunteer. Still at the age of 17, he became a commissioned officer. After the war and after finishing high school, he studied veterinary medicine in Gießen, where he subsequently became a research assistant in the Department of Microbiology and Hygiene with Elmar Roots. It was here that his life-long passion for virology originated. Rudi always considered meeting [Dr. Heinrich Werner Schäfer (born 1912)] at Gießen one of his greatest fortunes in life. Werner Schafer quickly recognized the extraordinary scientific talent of the young veterinarian, and offered Rudi a position at the Max Planck-Institut fur Virusforschung in T¨ubingen. In the fifties and sixties of the last century this was one of the world's leading virus research centers, and when Rudi went there it was in its hey-day. Gierer, Schramm, andWecker had discovered RNA genomes with plant and animal viruses. Anderer had elucidated the amino acid sequence of the TMV coat protein and was able to reconstitute the virus from RNA and coat protein. Schafer had discovered that fowl plague virus was an influenza virus and thus laid the foundation for the paradigm role of this virus in influenza virus research. He had also shown that fowl plague virus was an excellent model for studying the architecture and replication of enveloped viruses, in general. The hemagglutinin, the nucleocapsid protein and other viral components had been recognized as different structural and functional entities, and Rudi became heavily engaged in their biochemical and immunological characterization. He was very successful in his research and was soon recognized as one of the most promising young scientists in his field.

In 1964 Rudi returned to his alma mater in Gießen as chairman of the new Department of Virology. Apart from at the Max Planck-Institut in T¨ubingen, virology was not well developed in Germany at that time. Rudi felt that the field could be promoted best by scientific excellence in an academic environment. The new institute was therefore conceived as a research institute. From the beginning the focus was on influenza viruses, and they remained the central issue for the three decades of Rudi's chairmanship, although the spectrum of viruses under investigation increased significantly later.

It soon became clear that influenza virus research at the new institute would follow two major tracks: (1) the elucidation of the structure of the virus genome and of the replication mechanisms, and (2) the analysis of the biosynthesis and function of the envelope constituents. Studies on molecular epidemiology and pathogenesis would follow and prevail in later years. The finding that influenza viruses have segmented genomes provided an explanation for their high genetic variability. In a classic study on the origin of human influenza virus subtypes H2N2 and H3N2 published 1978 in Virology, Rudi and [Christoph Scholtissek (born 1929)] showed that gene exchange was the mechanism underlying the emergence of new pandemic viruses.

Reassortants obtained in the laboratory became invaluable tools to address many important problems in influenza virology on a genetically well defined basis. Thus, it was shown that some of the reassortants derived from two apathogenic parent viruses had acquired pathogenicity. Comparisons among many reassortants revealed that pathogenicity was associated with quite different gene sets. This led to the concept that pathogenicity depends on an optimum gene constellation rather than being defined by a single gene.

Among the viral glycoproteins investigated, the influenza virus hemagglutinin always played a prominent role.The observation that influenza virus infectivity depends on proteolytic activation of the hemagglutinin revealed that receptor binding is not the only function of this protein, it also mediates virus entry by membrane fusion. Equally important was the finding that hemagglutinin activation is a prime determinant of pathogenicity. In a series of studies that extended almost to the end of his scientific career, Rudi demonstrated how structural changes of the cleavage site altered pathogenicity, with heterologous RNA recombination as one of the most interesting mechanisms involved. Among the activating enzymes were also bacterial proteases, which proved to have a decisive effect on the development of pneumonia in co-infected animals.

Numerous other viruses interested Rudi. These included coronaviruses, infectious bursitis virus, papilloma viruses of rodents and birds, Borna disease virus (BDV), and paramyxoviruses. In fact, Rudi's observation that cleavage activation of a viral glycoprotein determines pathogenicity was first demonstrated with Newcastle disease virus and was later confirmed and extended by studies on Sendai virus, another paramyxovirus.

BDV was a particular challenge for him. This virus, which causes infections of the central nervous system (CNS), is endemic in horses and sheep in Central Europe and can be experimentally transmitted to other hosts. Rudi showed that the disease was the result of a T cell-mediated immuno-pathological reaction in the CNS. Disease symptoms vary depending on the host species and immune status, and Rudi was excited when he found that infection of tree shrews caused behavioural disorder. This prompted collaborative studies with clinical groups which showed that seroprevalence forBDV-specific antibodies was significantly higher in neuro-psychiatric patients than in controls. Whether BDV is indeed responsible for human neuro-psychiatric disorders is a matter of ongoing research in many laboratories.

Such a large scientific programme could only be successful with a clear conceptual framework. Rudi realized at a very early stage that elucidation of the pathogenetic mechanisms he was so much interested in would require a multidisciplinary approach combining virological, cell biological, molecular biological, biochemical and immunological expertise. This went well beyond the limits of his own Department, but with his enthusiasm, his charisma, and his scientific stature he was able to convince other groups that it was worthwhile to collaborate with him. Therefore Gießen was soon recognized internationally as a center of virology that over the years became the scientific home of numerous German virologists and the host of guest investigators from all over the world, many of whom were going to be Rudi's life-long friends. Highly ranked academic appointments and prestigious awards, such as the Robert Koch Prize, are documents of his extraordinary scientific reputation. However, despite all of this Rudi continued to be a dedicated researcher working at the bench until the end of his professional career. And he was never distracted from what he considered to be his prime mission, to work for the benefit of his Institute and his field.

Many of Rudi's former collaborators and friends met him last at a reunion on the occasion of his 75th birthday. He was marked by the disease which he had already fought then for some time, finding all the loving care he needed so much with his wife Renate, to whom he was married for almost 50 years. Those who were there and all of his other friends and colleagues will sorely miss him and remember him as a great scientist whose contributions to virology will live on.

2021 (Feb 22) - Yorkshire Post : "The Yorkshireman who named the coronavirus and aided its discovery"

A brilliant but modest Yorkshire scientist helped name the coronavirus and played a role in its discovery

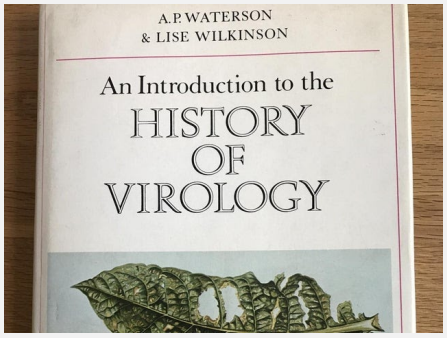
[HN01IO][GDrive]

Professor Tony Waterson who helped name the coronavirus in the 1960s

[HN01IP][GDrive]

Prof. Tony Waterson, left, a leading authority on viruses, holding a virus model with Prof Rudi Rott of Germany in the mid 1960s. They worked together on research.



[HN01IQ][GDrive]

Prof. Waterson was a leading authority on viruses

As Prime Minister Boris Johnson lay dangerously ill with Covid-19 in St Thomas' Hospital in London, he was unaware that decades earlier, in that very same hospital, a Yorkshireman had helped facilitate the discovery of the virus type that caused the devastating world-wide pandemic.

It was in Professor Tony Waterson's Microbiology Department at St Thomas' that the coronavirus was first identified in 1964 by June Almeida, a brilliant, Scottish-born scientist he had headhunted from the Ontario Cancer Institute in Canada.

Hornsea born Prof. Waterson and Dr David Tyrrell, then head of the Common Cold Research Unit, then took on the task of naming the virus with help from a dictionary. This initial discovery was the crucial first building block in helping modern day scientists battle this latest deadly strain.

The story began when the Common Cold Research Unit in Salisbury identified an unusual virus strain in nostril swabs taken from schoolboys. They found that it caused cold-like symptoms but had properties that were quite distinct from the familiar cold viruses and they were keen to find out more.

Dr David Tyrrell later wrote: "I decided to seek help from Tony Waterson, the new professor of virology at St Thomas' Hospital. "He had just recruited an electron microscopist, June Almeida, who was seemingly extending the range of the electron microscope to new limits. She claimed that she would be able to find virus particles with her new, improved techniques.

"We were not too hopeful but felt it was worth a try. The results exceeded all our hopes and her pictures revealed their structure beautifully. June was confident that these three viruses were something quite new."

The daughter of a Scottish bus driver who grew up in a Glasgow tenement and left school at 16 was right. Starting as a lab technician, she went on to study virology and became a leading light in virus imaging, identification, and diagnosis. What she saw that day 56 years ago was the first glimpse of a human coronavirus and she recognised that it was related to viruses in animals as she had seen similar particles while investigating mouse hepatitis and infectious bronchitis in chickens.

This new virus group needed a name and the circumstances of its coinage were recounted by Dr Tyrrell: "We sat down in Waterson's office to consider the implications of these results. We were quite certain that we had identified a previously unrecognised group of viruses. So what should we call them? "Influenza-like seemed a bit feeble, somewhat vague, and probably misleading. "We looked more closely at the appearance of the new viruses and noticed that they had a kind of halo surrounding them. Recourse to a dictionary produced the Latin equivalent, corona, and so the name coronavirus was born."

It was in a short article in the journal Nature in November 1968 that Dr June Almeida, Dr David Tyrrell and six other virologists first used the name "coronavirus" in print.

Prof. Waterson's son Nicholas says that it was only after the start of the pandemic last year that the family became aware of their father's involvement with the work, after looking through his papers and books. "We knew, of course, that he did something clever with viruses and we were even sometimes allowed to peer down the electron microscope on visits to his lab but we really had no idea what he got up to in any detail," says Nicholas. "He died when I was only 18 and learning about this has made me feel closer to him again after so many years."

Just over fifty years ago, in 1970, Prof. Tony Waterson wrote the following somewhat prescient words: "If a pathogenic micro-organism should break loose, which can spread not only from animals to man but also readily from man to man, a major and global disaster would happen."

Dying prematurely in 1983, at the age of 59, he did not live to see the viruses he had named finally cause the global pandemic he had feared. Dr June Almeida passed away in 2007 and Dr David Tyrrell in 2005 but their work also lives on.

*A LIFE SCIENTIFIC: Professor Tony Waterson was born at the Old Hall in Hornsea on the East Yorkshire coast in 1923. His parents had just moved north from Kent after buying Hornsea College, a girl's boarding school based in a rambling Jacobean manor house. Gladys, his mother, became the headmistress and it seems that she was a woman with enormous drive as she was still only in her twenties when she took on the role.

She set the bar very high not only for her pupils but also her own children., though Trevor's son Edward Waterson who lives in York, says: "Tony and his older brother, Trevor, were very close and enjoyed a carefree seaside childhood in what was then a quiet little seaside town."

The young Tony was enrolled at Hornsea College and then sent off to board at the age of only seven at Orleton Preparatory School up the coast in Scarborough. Though he missed his family and objected to cliff-top football in the bracing Yorkshire winds, he threw himself into his schoolwork and excelled academically.

When it came to his secondary schooling, Tony was sent south, winning a scholarship to Epsom College in Surrey and later won a classics scholarship to Emmanuel College, Cambridge in 1941. Despite his lifelong love of Latin and Greek, he chose to follow a more practical scientific path, graduating with a double first in Natural Sciences.

He had been due to be called up for military service in 1943 but according to College archivist Amanda Goode, Emmanuel fought successfully to keep him, arguing that he was one of the "very best" students. It was also at Cambridge that Tony discovered the Christian faith that would guide him through the rest of his life. After completing his medical studies at the London Hospital, he did National Service as an RAF Medical Officer in Germany, looking after servicemen and their families during the Berlin airlift.

His daughter Sarah says that there was always a caring side to him. She recently found a letter he wrote to his mother asking her to send a tin of cocoa from Yorkshire as there was none to be had in Germany and his German teacher wanted some for his elderly mother.

Following National Service, his scientific career took off fast. He returned to Cambridge to lecture and research in pathology, specialising in viruses, and after a sabbatical year back in Germany, he took up the post of Professor of Microbiology at St Thomas's Hospital in London in 1964 at the age of 40. Later he would become the first Professor of Virology at the Royal Postgraduate Medical School at Hammersmith Hospital.

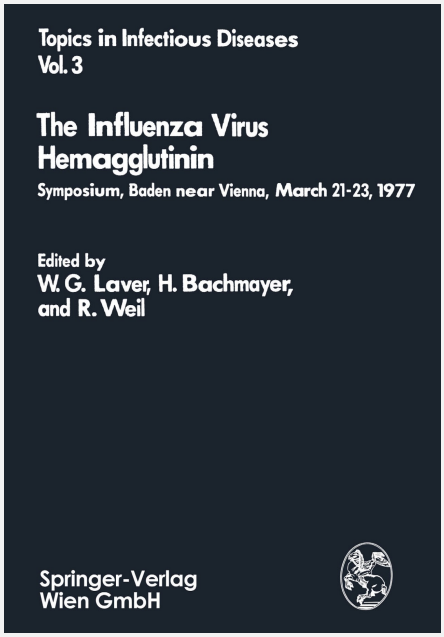
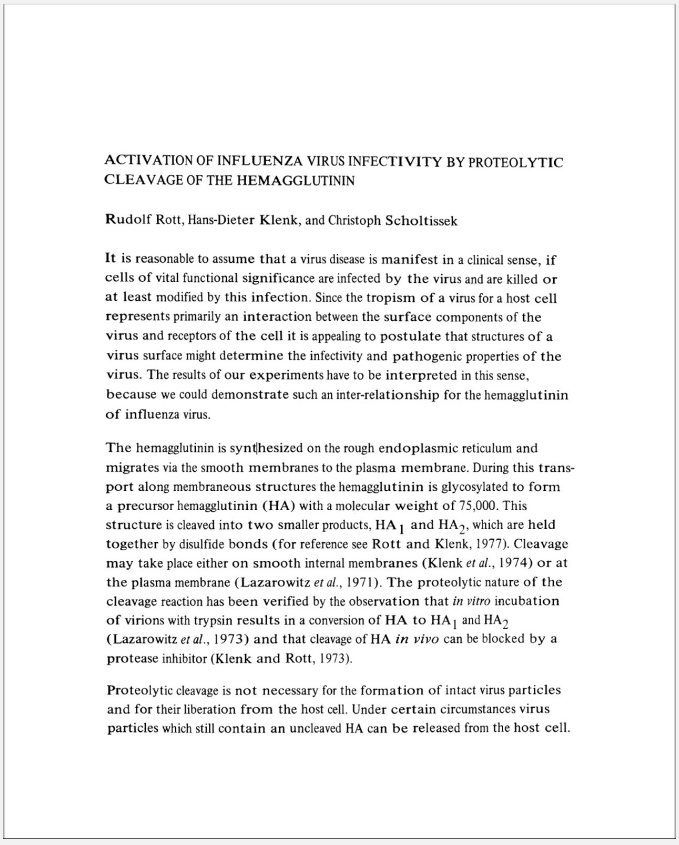
Abstract

"It is reasonable to assume that a virus disease is manifest in a clinical sense, if cells of vital functional significance are infected by the virus and are killed or at least modified by this infection. Since the tropism of a virus for a host cell represents primarily an interaction between the surface components of the virus and receptors of the cell it is appealing to postulate that structures of a virus surface might determine the infectivity and pathogenic properties of the virus. The results of our experiments have to be interpreted in this sense, because we could demonstrate such an inter-relationship for the hemagglutinin of influenza virus."



[HI002J][GDrive]



ACTIVATION OF INFLUENZA VIRUS INFECTIVITY BY PROTEOLYTIC CLEAVAGE OF THE HEMAGGLUTININ

Rudolf Rott, Hans-Dieter Klenk, and Christoph Scholtissek

It is reasonable to assume that a virus disease is manifest in a clinical sense, if cells of vital functional significance are infected by the virus and are killed or at least modified by this infection. Since the tropism of a virus for a host cell represents primarily an interaction between the surface components of the virus and receptors of the cell it is appealing to postulate that structures of a virus surface might determine the infectivity and pathogenic properties of the virus. The results of our experiments have to be interpreted in this sense, because we could demonstrate such an inter-relationship for the hemagglutinin of influenza virus.

The hemagglutinin is synthesized on the rough endoplasmic reticulum and migrates via the smooth membranes to the plasma membrane. During this transport along membraneous structures the hemagglutinin is glycosylated to form a precursor hemagglutinin (HA) with a molecular weight of 75,000. This structure is cleaved into two smaller products, HA_1 and HA_2, which are held together by disulfide bonds (for reference see Rott and Klenk, 1977). Cleavage may take place either on smooth internal membranes (Klenk *et al.*, 1974) or at the plasma membrane (Lazarowitz *et al.*, 1971). The proteolytic nature of the cleavage reaction has been verified by the observation that *in vitro* incubation of virions with trypsin results in a conversion of HA to HA_1 and HA_2 (Lazarowitz *et al.*, 1973) and that cleavage of HA *in vivo* can be blocked by a protease inhibitor (Klenk and Rott, 1973).

Proteolytic cleavage is not necessary for the formation of intact virus particles and for their liberation from the host cell. Under certain circumstances virus particles which still contain an uncleaved HA can be released from the host cell.

[HI002K][GDrive]

ACTIVATION OF INFLUENZA VIRUS INFECTIVITY BY PROTEOLYTIC CLEAVAGE OF THE HEMAGGLUTININ

It is reasonable to assume that a virus disease is manifest in a clinical sense, if cells of vital functional significance are infected by the virus and are killed or at least modified by this infection. Since the tropism of a virus for a host cell represents primarily an interaction between the surface components of the virus and receptors of the cell it is appealing to postulate that structures of a virus surface might determine the infectivity and pathogenic properties of the virus. The results of our experiments have to be interpreted in this sense, because we could demonstrate such an inter-relationship for the hemagglutinin of influenza virus.

The hemagglutinin is synthesized on the rough endoplasmic reticulum and migrates via the smooth membranes to the plasma membrane. During this transport along membraneous structures the hemagglutinin is glycosylated to form a precursor hemagglutinin (HA) with a molecular weight of 75,000. This structure is cleaved into two smaller products, HA 1 and HA2, which are held together by disulfide bonds (for reference see Rott and Klenk, 1977). Cleavage may take place either on smooth internal membranes (Klenk eta!., 1974) or at the plasma membrane (Lazarowitz eta!., 1971). The proteolytic nature of the cleavage reaction has been verified by the observation that in vitro incubation of virions with trypsin results in a conversion of HA to HA 1 and HA2 (Lazarowitz et at., 1973) and that cleavage of HA in vivo can be blocked by a protease inhibitor (Klenk and Rott, 1973).

Proteolytic cleavage is not necessary for the formation of intact virus particles and for their liberation from the host cell. Under certain circumstances virus particles which still contain an uncleaved HA can be released from the host cell.

Particles with a precursor HA or the hemagglutinin composed of the cleavage products HA 1 and HA2 are equally capable of a hemagglutination reaction, and in both cases the hemagglutination can be inhibited by specific antisera. This means that the reactive antigenic determinant is not significantly modified

by proteolytic cleavage. The same holds true for the interaction of the hemagglutinin with the host cell. In all systems tested cleavage was not necessary to establish adsorption of virus particles to neuraminic acid containing receptors at the cell surface. A cleaved HA is necessary, however, for the infectious process to proceed further (Klenk eta/., 1975; Lazarowitz and Choppin, 1975).

Infection of embryonated chicken eggs or cells derived from the chorioallantoic membrane of the chick embryo with influenza strains of human and animal origin results in the formation of infectious progeny virus. Attempts to grow infectious viruses in chick fibroblasts are only successful with strains which possess the hema.gglutinin of fowl plague virus (FPV), while all others have only a negligible infectivity. Analyses in polyacrylamide gels show a direct correlation between infectivity and the structure of the hemagglutinin. Only particles with a cleaved HA are infectious. A successful cleavage of HA which corresponds to productive conditions in vivo can be carried out in vitro by treating the inactive virus particles with trypsin. Such a treatment also activates infectivity (Table 1).

A productive infection of cells in which infectious virus is normally not formed is attained if trypsin is added to the culture medium. This becomes particularly evident, if cells are infected under single and multiple cycle conditions with a multiplicity of infection ranging from 30 to 0.003 PFU/cell (Figure 1). Growth curves of FPV which is synthesized in such cells as infectious particles with cleaved HA are identical irrespective of the presence of trypsin. On the other hand a clear requirement for the enzyme is observed in the case of virus N.

When trypsin is present in the medium, replication is similar to that of FPV. In the absence of trypsin, however, newly synthesized non-infectious virus is only demonstrable under single cycle conditions. Under multiple cycle conditions virus production progressively decreases as the multiplicity of infection is reduced. This phenomenon also explains plaque formation by such strains which are normally non-plaque producers in chick fibroblasts in the presence of trypsin (Figure 2).

Whether a proteolytic cleavage is possible in a given host cell is determined primarily by the individual structural characteristics of the HA rather than by the activation of cellular proteases by the infecting virus. This could be demonstrated by double infection of chicken fibroblasts with FPV and virus N, which are produced in highly infectious form or with reduced infectivity, respectively.

Since HA 1 and HA 2 have different electrophoretic mobilities in FPV and virus N, it was possible to determine the origin of the cleaved HA in the mixed virus population by coelectrophoresis with homogeneous preparations of each virus.

The glycoprotein pattern of the progeny virus is shown in Figure 3. The results show clearly that after double infection FPV does not induce cleavage of the hemagglutinin glycoprotein of virus N. Biological tests confirm our previous observation that virus N requires try;>sin to undergo multiple cycle replication in chick fibroblasts, whereas FPV can do so in the absence of the enzyme. In doubly infected cells only FPV-specific hemagglutinin is formed if trypsin is absent. In the presence of trypsin, however, hemagglutinin of both strains can be detected (Table 2).

[...]

Comparisons of the nuclear magnetic resonance (NMR) spectra of chicken fibroblasts exposed to virus N with either cleaved or uncleaved HA are being carried out in our laboratory by C. Nicolau and H-D. Klenk. The results suggest that the hemagglutinin is in fact involved in the penetration process. These studies indicate that virus N with cleaved HA induces an alteration in the fluidity of the lipid bilayer of the plasma membrane, whereas virus N containing uncleaved HA does not. Simitar but more distinct fluidity changes have been observed when Newcastle disease virus containing a biologically active fusion glycoprotein has been compared to virus containing an inactive F glycoprotein.

This could mean that the mechanisms of penetration process resemble each other in both cases and that the function, which is exerted by the F glycoprotein of paramyxoviruses must be attributed to the hemagglutinin of influenza viruses.

Since a hemagglutinin composed of the cleavage products of HA 1 and HA2 is indispensable for the formation of infectious virus particles, only those conditions which have been def"med in our in vitro studies can predispose to a pathological situation in the host organism. In contrast to former conclusions from others it is now clear, however, that viral glycoproteins alone do not determine pathogenicity of influenza viruses. This could be convincingly deduced from a series of experiments, where recombinants of fowl plague virus were compared in vitro and in vivo (Rott et al., 1976). In these experiments there was no correlation between the presence of cleaved glycoproteins and the pathogenicity of the virus. Furthermore, using the same parent recombinants for double infection, the progeny back recombinants were only infrequently pathogenic for chicken, although they carried both surface antigens of the highly pathogenic FPV (Table 5). The results of these experiments show clearly that the pathogenicity of influenza virus depends on more than one gene. This conclusion was underlined by experiments (Table 6) where FPV recombinants were employed which carried a particular defined gene from other influenza viruses (Scholtissek et al., 1977). Here again it became clear that the FPV derived HA cannot induce the disease in the natural host, but a certain gene constellation is necessary to make up a pathogenic virus. Full reconstitution of pathogenicity to levels of the wild type FPV largely depends on the parent strain being used for the gene exchange and the particular gene which is carried 0'Ä~er. This means again that there is no individual gene coding for pathogenicity and that the HA gene is not a 'virulence' gene by itself.

At the present time we cannot list the optimal gene constellation to make up a pathogenic virus and we are not in a position yet to define the particular contribution made by the individual genes which might finally result in the complex phenomenon of pathogenicity.

Institute for Medical Virology Giessen - Institut für Medizinische Virologie

Institut für Medizinische Virologie Gießen

The **Institute for Medical Virology** has been a research facility at the Justus Liebig University of Gießen since 1966 . The institute emerged from interdisciplinary research in the veterinary, human and biological departments and, when it was founded, housed the first independent chair for medical virology in what was then the Federal Republic of Germany. The first professor was Hans Joachim Eggers (1966–1972) followed by Heinz Bauer (1973–1990, President of the University of Gießen from 1987), Wolfram H. Gerlich (1991–2010) and John Ziebuhr (since 2010). The institute was national from 1996 to 2010Consultative laboratory for hepatitis B and hepatitis D viruses of the Robert Koch Institute and has been the national reference center for HBV and HDV since 2011 . It has been part of the German Center for Infection Research since 2012 .

history

Giessen virology until the institute was founded

The earliest work on virus infections at the Institute for Hygiene of the Faculty of Human Medicine in Gießen can be traced back to Georg Gaffky (1850–1918), Robert Koch's colleague and later successor . The research was limited to disease descriptions, as the viruses had not yet been characterized as an independent infectious agent and cultivation in the laboratory was not yet successful. Rudolf Otto Neumann (1868–1952) dealt with rabies infections in 1912 , but research into viral infections was not yet an independent subject and remained until the development of cell culture and electron microscopy an exotic branch of hygiene and bacteriology.

With the support of the Hygiene Institute of the Medical Faculty, the Veterinary Medicine Faculty, which has been independent since 1914, founded its own institute for veterinary hygiene , bacteriology, veterinary police and animal disease studies in 1924 (from 1926 Institute for veterinary hygiene and animal disease studies). Wilhelm Zwick (1871–1941), as the first full professor of the new chair, mainly dealt with viral diseases, including rinderpest and Borna's disease . Zwick pursued the plan to set up a Kaiser Wilhelm Institute for animal disease research in Giessen, but this was achieved through the synchronizationthe university from 1933 and the death of Zwick was not realized. After the war Elmar Roots (1900–1962) took over the veterinary institute and deepened the focus on virology even further. In 1955 he acquired the first transmission electron microscope and ultracentrifuge from the University of Giessen; In addition to cell culture, these were the fundamental apparatus on which virological research was based until the 1960s. Rudolf Rott (1926–2003), who after a short stay at the "Max Planck Institute for Virus Research" in Tübingen (now the MPI for Developmental Biology), did his doctorate at Roots) completed his habilitation at Roots and was appointed to the first chair for virology (Faculty of Veterinary Medicine) in Gießen in 1964.

Due to the division of labor in the faculty structure, according to which virological topics were strongly represented at the veterinary medicine faculty since 1924, no separate department for virology was created at the human medicine institute for hygiene and bacteriology. This deviates from the usual development of other virological institutions in German-speaking countries. The fact that virology was not represented independently in the human medicine faculty was particularly

evident from Rott's research focus, which deals with influenza viruses together with Christoph Scholtissek and Rudolf Dernickbusy. These viruses represent in a special way the interaction between human and animal infections. For a planned virological research network on site and its expansion in a planned special research area , an independent medical chair was required, which was established in 1966 and to which Hans Joachim Eggers was appointed on June 23, 1966. Eggers discovered the RNA polymerase of the poliovirus at Rockefeller University in New York and characterized its mutations after he had previously obtained his doctorate at the MPI for Virus Research in Tübingen.

The first laboratories of the new institute were located behind the institute for poultry diseases in a former stable building on Gaffkystraße. Like its partner institute for veterinary medicine, it was named “Institute for Virology”, but with the addition “Department of Human Medicine”. To avoid confusion, the term Institute for Medical Virology became more and more common in the 1980s.

SFB 47 and MZI building

Eggers and Rott designed what was then a new type of research association, which in 1968 resulted in the establishment of the Collaborative Research Center 47 “Mechanisms of Viruses Pathogenicity”. This brought together other research groups at the university, such as biochemistry, pharmacology, microbiology and later plant virology. A research group emerged from the CRC 47, which existed exceptionally long until 1988, and Rott also remained its spokesperson until his retirement in 1994. When the SFB was founded, the premises were limited and in 1968 the university began building an interdisciplinary research center in Frankfurterstrasse 107, the so-called multi-purpose institute (MZI), which was considered exemplary at the time. This building was tailored to the needs of the SFB and, after its successive occupation in 1970/1972, housed all the relevant institutes of the research association. The bundling of three virological institutes (veterinary virology, human virology and plant virology) in a single research building was unique in Europe at the time.

In 1970 Eggers accepted Hans-Dieter Klenk, who had come from New York, as an assistant in the Institute for Medical Virology, with which the veterinary-virological working groups on influenza viruses found a human medical supplement. A research group around Gisela and Gerd Wengler was also set up to deal with other RNA viruses, the alpha and flaviviruses . The first head of the newly established diagnostic department was Jan Leidel , who followed Eggers to Cologne University in 1973.

In 1973, Heinz Bauer , who came from the MPI in Tübingen, established the then still young research area of retrovirology at the institute , became the new chair holder . In the same year, Hans-Dieter Klenk received a C3 professorship at the institute, which he held until he was appointed to the Institute of Virology in Marburg in 1985. Heinz Bauer became President of the Justus Liebig University in 1987, which meant that the chair remained vacant for a long time. The retrovirologist Roland Friedrich, who was appointed to the C3 professorship in 1986 and comes from the laboratory of Michael Bishop and Harald Varmus in San Franciscotook over the provisional management of the institute. He devoted himself to the study of virus-induced leukemia , in particular the Friend leukemia virus .

The "Giessen School of Virology"

From the beginning, many research groups worked at the institute, from which nationally and internationally important virologists emerged. In addition to Hans-Dieter Klenk (Director of the Institute for Virology in Marburg), this group, known as the “Giessen School of Virology”, also includes Robert Friis , Teruko Tamura , Heiner Niemann (Director of the Friedrich Loeffler Institute), Angelika Barnekow (professorship at the University of Münster), Helga Rübsamen-Schaeff (Director of the Georg-Speyer-Haus), Bernhard Fleischer (Director of the Bernhard Nocht Institute for Tropical Medicine) and Masanori Hayami (Director of the Virus Research Institute, Kyoto).

SFB 535 and consulting laboratory

Bauer's successor as director was Wolfram H. Gerlich in 1991 , who previously worked at the Göttingen Institute for Hygiene under Reiner Thomssen (Head of the Medical Microbiology Department, Center for Hygiene and Human Genetics at the University of Kreuzbergring 57) and at Stanford University under William S. Robinson on the hepatitis B virus(HBV) had worked. The Göttingen Institute was then the national reference center for hepatitis viruses. Among other things, Gerlich characterized the surface protein of HBV (HBs antigen) and discovered for the first time the covalent binding of a protein to a viral genome. With his appointment, further employees gradually came to Gießen from Göttingen, who dealt with various aspects of the *Hepadnaviridae* and the then newly discovered hepatitis C virus .

Since the SFB 272, which emerged from the SFB 47 and was initiated by Gerd Hobom , existed at that time and was only granted a short application period foreseeably, Gerlich established a new SFB from 1995, which, following on from the existing interdisciplinary structures in Giessen, also added virological Should involve research groups from Marburg. This was finally achieved in 1997 with the SFB 535 (Invasion Mechanisms and Replication Strategies of Pathogens). This SFB 535, coordinated by the Institute for Medical Virology, existed in the maximum application period until 2009 and significantly shaped the infection research of various institutes in Giessen.

In 1996, the institute was appointed the national consultative laboratory for hepatitis B and D, which entrusted it with issues of standardization, clarification of transmission cases, the efficiency of vaccine preparations, test procedures and procedures for virus inactivation and virus safety with regard to HBV and HDV, among other things at national and international level . The ongoing close cooperation with the WHO , the Paul Ehrlich Institute and the Robert Koch Institute date from this time .

New research building

With Gerlich's retirement in 2010, the tasks as a consulting laboratory ended as intended, and in the previous year the maximum duration of the SFB 535. With the appointment of virologist John Ziebuhr from Queen's University Belfast , the chair could be filledagain in the same year. Ziebuhr previously worked in Würzburg on the molecular biology of coronaviruses and was involved in the characterization and detection of the SARS coronavirus in China. After the end of the consulting laboratory, the tasks of such a laboratory were redefined by the RKI and, due to the increased importance of the pathogens, an upgrade to the reference center was recommended and advertised as such. After a new selection process in 2011, the institute wasFederal Ministry of Education and Research appointed National Reference Center (NRZ) for hepatitis B and D viruses.

Reference Center (NRZ) for hepatitis B and D viruses.

The planning of a new research building for the institutes of the MZI had been advanced since the 1990s. After construction delays, the institute was able to move to the new Biomedical Research Center Seltersberg (BFS) in March 2012 , as the work in the MZI building, which is now over 40 years old, no longer met the requirements for virological work. Ziebuhr was elected the first spokesman for the FSO. In 2012, together with the Marburg virologist Stephan Becker, he succeeded in founding the SFB 1021 (*RNA viruses: RNA metabolism, host response and pathogenesis*), which brings the three virological institutes (veterinary and human virology in Gießen, human virology in Marburg) together again to form a research network. In the same year the Institute for Medical Virology became part of the German Center for Infection Research .

Hans-Dieter Klenk

Rudolf Rott (1926–2003) –
Ein Leben für die Virusforschung

http://geb.uni-giessen.de/geb/volltexte/2004/1882/pdf/Klenk-gu37-2004.pdf

With this sentence Rudolf Rott wrote on October 6th 2000 at the beginning of his commemorative speech placed on his teacher [**Dr. Heinrich Werner Schäfer (born 1912)**], wants i start. He brings it in a few words all that expresses us - just once two and a half years later - at the news moved by Rudi's death. Dear Renate, Dear Sabine, you know that many of us back then and during the previous weeks and months when the end with inexorability often in my mind You guys were. The academic celebration to which we got together here today will the grief cannot suppress, but alleviate it in kind and grateful remembrance to a great scientist, one model academic teacher and one good friend.

I met Rudolf Rott in September 1970 learned when I came from New York an assistant position in the virological institute at the medical faculty with Hans Eggers. It turned out very quickly that Rudi and me the same scientific Interests connected. From the collaboration, which actually started immediately and lasted for more than 15 years a personal friendship that soon also included families. I have Rudi almost everyone during my time in Giessen Day seen, and also later is the regular one Contact never torn off. In the rain He used to come to see me after 6 o'clock in the evening come, and then maybe stayed a quarter, but often an hour or two. Such He not only made visits to me, they were for most employees. Yoshiyuki Nagai, from 1974–1976 visiting scholar in Giessen and later professor at the University of Tokyo, describes this in a letter he sent me on the occasion sent today as follows:

> *Rudi "used to stroll into each lab, almost every day and to take at least a few minutes and sometimes an hour to discuss the data just coming out. Hey what casual and light-hearted in manner, sometimes cracking a joke, but was essentially very eager to share his rich experience and knowledge on animal viruses with us of the younger generation. "*

These conversations weren't all about Science, but often about God and the world. By telling what moved him and drove what he experienced in the present and Past, he allowed me over and over again Insights into his life that go far beyond the scientific went out. Its openness and spontaneity, its intellectual agility made access to his person light.

Youth, academic education

Rudolf Rott was born on May 23, 1926 in Stuttgart born. The father, a government building officer, came from a German resident in Ukraine Family and had his home during abandoned during the First World War. The family of Mother was rooted in Swabian. In different Share Württemberg - in Ellwangen, Oberndorf and Rottweil - Rudi has them Attended school. Has Swabian origin he can never deny it. His youth fell in a time by one by the national governor socialism has so far sparked a spirit of optimism was shaped to an unknown extent. who Rudi's enthusiasm knows the one Was part of his being and which he was about to be has preserved throughout life, can Easily imagine the fascination that this awakening in a supposedly better future evoked the adolescent.

1943, still Before leaving school, he volunteered as a war volunteer and stood as an officer at the age of 18 at the frontline. 2 years later - he was just once 19 - it was all over: captivity, Internment camp. The ideals had each other proved to be illusions. The enthusiasm was given way to knowledge, to the wrong thing to have served. Reiner Thomssen has this everything in his poignant funeral speech on 5. May be described with empathy and fairness. Rudi himself has this past never suppressed. She left a traumatic impact on him. How could it have been otherwise?

But the collapse also offered an opportunity for a new beginning. In 1947 Rudi was still in the Graduated from high school. Then he worked for 2 years long as a servant for a farmer in Hohenlohe. He liked to think back to that time. May also be one of the motifs for the study of veterinary medicine lie that he started in Giessen in 1950. 1955 PhD he on the topic "A Contribution to Etiology the pig flu "with Prof. Roots, whose Assistant he then still in the 3 following Years ago.

During this time he met Renate Kröll who later became his wife. In almost 50 Years of marriage she stood him in love and care and, anytime his temperament of needed to balance wisely aside. The Daughter Sabine and the 3 grandchildren were his pride and joy. He was ingrained in this Family, it gave him strength and confidence. Rudolf Rott also met [Dr. Heinrich Werner Schäfer (born 1912)] in Giessen Schäfer, who was a private lecturer here at the time Held lectures. The two quickly took hold Trust each other, and Rudi has this meeting later again and again as one of the fortunes of his life. When Shepherd who is the extraordinary scientific Talent of the young veterinarian quickly realized an assistant in his department at the Max Planck Institute for Virus Research in Tübingen, Rudi immediately accepted. In the In the 50s and 60s it belonged to Tübingen Institute one of the leading international institutions in the field of virus research. When Rudi arrived, it was in full bloom. Greed, Schramm and Wecker had the RNA genomes discovered by plant and animal viruses. Another had the amino acid sequence of the tobacco mosaic virus cleared up and the virus from RNA and Protein reconstituted in vitro. Schäfer had found that the virus is the classic avian influenza was an influenza virus, and with it the Created the basis for the paradigmatic role, who then research this virus this virus group should play. He could also show that the avian influenza virus in an excellent way to study Structure and reproduction of enveloped viruses completely generally suitable. Hemagglutinin and nucleocapsid protein were in the beginning as building blocks the virus particle has been identified, and Rudi now dealt intensively with her biochemical and immunological characterization. The successes were not lacking. Soon it was valid as one of the most hopeful young virologists.

So it was only logical that the 36-Year olds running the at his alma mater Giessen newly founded Institute for Virology was offered. Of course it wasn't a coincidence that this chair, next to Würzburg the first of its kind in Germany, just working on one Faculty of Veterinary Medicine established virology has always been crucial Receive impulses from veterinary medicine. So I would like to briefly get to the roots of our subject here in Giessen. After this Wilhelm Zwick, from internal medicine coming, in 1924 the newly created ordinariate for veterinary hygiene and animal diseases took over, was increasing in this faculty researched about viral diseases. Already Zwick's research on the Borna's disease and its causative agent Laid the foundations for a research area, which developed to full bloom under Rudolf Rott has been. **The end of the 30s by [Dr. Erich Traub (born 1906)] results obtained on the lymphocytic cells Mouse choriomeningitis not only set current paradigm for a virus-induced, immunopathological Reaction represented, but formed also an essential basis for discovery of the phenomenon of immunological Tolerance. In the 50s was busy Elmar Roots, later Rott's doctoral supervisor, successful with the causative agent of psittacosis, which then was still counted among the major viruses, and with the rabies virus.**

It was also Elmar Roots who initiated the game in 1962 the institute for To divide up veterinary hygiene and animal disease. The rapid development of the microbiological Taking into account subjects were after his sudden death next to that Institute for Hygiene and Infectious Diseases of the animals the Institute for Poultry Diseases as well as bacteriology and virology as independent chairs set up. After The conception of the faculty at that time should be the Primarily doing basic research in virology and such an addition and expansion of the other's scientific spectrum microbiologically oriented facilities of the faculty.

On April 15, 1964 the time had come. Rudolf Rott moved into a newly furnished, almost finished one put stable building that in a short time so That had been rebuilt the requirement were fulfilled for experimental work. For the necessary renovation work stood for a total of 30,000 DM and for them Initial equipment 120,000 DM available. Employees from the very beginning were next Ms. Seitz, who high her boss as everyone's esteemed institute secretary accompanied to the end hat, Rudolf Dernick and [Christoph Scholtissek (born 1929)] from the Max Planck Institute for Virus Research in Tübingen and Hermann Becht, who from Zurich joined them. Your commitment, yours scientific qualification and the common Willing to do good research in pouring the institute has an essential role in running owe its successful start to the then also led to it some years was able to move into a larger building later, in which it is still now.

Scientific work

Thus conditions were created under which focus on the scientific and organizational Rudolf Rott's talent in full bloom could unfold. It is impossible to do this in more than 300 publications laid down life's work, on which more than a hundred employees were involved and trained in a short memorial speech even approximately fully describe. I must therefore limit myself to a few focal points and wants the selection - without chronological Ranking - from two points of view to meet:

1) Where are Rudolf Rott's outspoken Pioneering achievements? "What did he discover?" was that of Otto Warburg again and again asked question when he was about importance and to judge the genius of a scholar would have.

2) Which structures did he create, which ones He set synergisms in motion, that of the virological research on his own Work area benefited?

As mentioned earlier, the new Giessen institute looked its most important task in the extraction newer and not so much in mediation known findings. So it was his Self-image according to primarily one Research institute. The research was after one that is clearly recognizable from the start scientific and organizational concept carried out. On the organizational I will come back to the concept later. The scientific concept was one Virus system from as many different ones as possible To illuminate angles. These Multidisciplinarity was with Rott as virologist, [Christoph Scholtissek (born 1929)] as a molecular biologist - a term which didn't even exist back then - and Becht as an immunologist in principle already in the first Hour. The object to which she their concentrated efforts were like the influenza viruses already in Tübingen. they should the central one for the entire 30 years Remain topic even if the range of Virus systems was later expanded considerably.

Early studies of influenza viruses

One of the themes of the early Gießen work had the structure and replication of the influenza virus RNA to content. From investigations for the so-called multiplicity reactivation there are already first indications of the segmented Genome structure (1). With the help of the virus-specific Polymerase made it possible to make complementary To produce RNA. This allowed again first studies on genetic Relationship between different Influenza viruses (2). Other work of the early phase dealt with the Surface proteins of influenza viruses. So could the neuraminidase by protease treatment cleaved from the virus and enzymatically active form (3). This approach has been used by other laboratories pursued further and ultimately led to X-ray structural analysis of

neuraminidase and for the development of neuraminidase inhibitors, which in recent years as drugs to fight influenza on the market arrived.

Overall, these works reflect a period of careful scanning and searching according to the main thrusts. In the beginning but it was already becoming apparent that influenza virus research is moving in two directions should move, one of which the Elucidation of the genome structure and the replication Mechanisms, but the other is research of biosynthesis and function the content of the virus envelope components. These are strongly molecular and cell biological specific subject areas will later be overlaid by two now completely virologically oriented research areas, namely the molecular Epidemiology and Phylogenesis, as well as the Influenza virus pathogenicity.

The influenza virus genome

One of the most important discoveries in the field influenza virus research was the center observation made in the 1970s that the Virus genome from 8 different RNA Segmenklenk ten, each of which for at least encodes one of the viral proteins (4). That was the explanation for the exceptionally high Influenza virus plasticity and variability found. The segmented genome structure enables namely the free exchange of Genes if a cell is affected by different influenza viruses is infected. Under these conditions Then new viruses can arise, the genes both parents included.

Structure, function and biosynthesis the glycoproteins of influenza viruses

The second focus of the research was the glycoproteins of the influenza viruses that carry the Initiators of the infection process and that Main goal of the immune defense of the infected organism are. Especially investigations on Hemagglutinin have been shown to have these viral components on the endoplasmic reticulum formed and transported from there to the cell surface become (5). In these investigations hemagglutinin appeared for the first time in his Significance as a biological probe, which later became broad Application in the education of the constitutional Exocytosis path found.

Of particular interest were the ko- and post-translational modifications that occur during The maturation process of the glycoproteins takes place. Studies with specific inhibitors contributed significantly to elucidate the glycosylation processes and the function of the carbohydrates at (6, 7). In the acylation was another previously unknown form of protein modification discovered (8). One of many viral glycoproteins observed modification is the proteolytic cleavage. In pouring could be shown that the cleavage of hemagglutinin due to cellular proteases for the infectivity of influenza viruses (9). It is important that the cleavage occurs exactly the place provided for this purpose (10). These findings then led to the discovery that hemagglutinin not just a receptor binding protein, but also a fusion protein. Plays a central role in the merger process a fusion peptide that - through the proteolytic cleavage released - to amalgamation of the virus envelope and cell membrane and so the introduction of the virus genome into the cytoplasm (11).

Studies on the influenza C virus showed that this virus has only one glycoprotein, that has the functions of a hemagglutinin, a Fusion factor and a receptor-destroying one Enzyme combined in itself (12). It differs the influenza C virus is very distinct from the influenza A and B viruses in their receptor specificity. These investigations resulted then also to the discovery of a new receptor-destroying one Influenza virus enzyme, thereby the high receptor specificity of the various influenza viruses underlined becomes.

Pathogenicity Mechanisms for influenza viruses

There was an instrument in the influenza assortment available with which a variety of biologically interesting problems approached on a genetically well-defined basis could be. So they were of great importance in finding the factors that responsible for the pathogenicity of influenza viruses are (13). These investigations have z. B. shown that non-pathogenic reassortants by mutation to pathogenic viruses can reverse (14). In the different Reassortants depended on the pathogenic properties of different gene constellations from. It turned out to be difficult to establish general rules according to which certain genes aim at Pathogenicity change are exchanged can. Overall went from this work suggests that pathogenicity is not due to a single one Gene can be defined, rather that they are more likely the result of an optimal Gene constellation is.

New impulses for pathogenicity research came from the investigations to the proteolytic Activation of hemagglutinin, the then a large one as a specific protein Assigned importance as a pathogenicity determinant could be. Examinations, which was initially carried out on avian influenza viruses were showed that the cleavage of hemagglutinin the spread of infection and thus the pathogenicity (15), but also the Adaptation to a new host (16) is essential influenced. Of the numerous works in which has been shown to be structural Changes at the cleavage site of the hemagglutinin lead to changes in pathogenicity, I just want to mention one here, in the heterologous Recombination with cellular RNA for blamed such an event could be (17). Finally, it should be remembered be that proteolytic activation of hemagglutinin is an important mechanism is also used by bacteria to increase pathogenicity an influenza virus infection lead (18).

Pathogenicity Mechanisms in paramyxoviruses

The proteolytic activation of surface glycoprotein also has with many others Viruses are of great biological importance. In In fact, the role that activation played the pathogenicity plays, for the first time at Newcastle Chicken Disease Virus (NDV) observed (19). Investigations later on Sendai virus, another paramyxovirus, have carried out this concept confirmed in principle (20). Yoshiyuki Nagai brings the importance of these investigations and the catalytic function that Rudi Rott played to the point when he writes:

> *"What was believed at that time was that paramyxovirus fusion glycoprotein synthesized in tissue culture cells would generally be inactive and become activated by treatment with a low dose of trypsin in vitro. What I was actually seeing in Gießen was, however, that the fusion protein of NDV was always proteolytically cleaved and activated in tissue culture cells. One day, looking at these data, Rudi said, just casually as usual, 'the strain Italy (you are using) is highly pathogenic (for chickens) '. Then it flashed across my mind that NDV would represent a useful or perhaps the best model to study the molecular basis of viral pathogenesis. Upon my request, Rudi immediately collected a panel of virulent and avirulent NDV strains. Using this panel, I was soon able to show a perfect correlation between the cleavability of fusion glycoprotein and virulence. "*

And he concludes:

> *"With this, we were able to open a new field, the molecular basis of viral pathogenesis. "*

Influenza Virus Evolution

The elucidation of the segmented genome structure was fundamental to understanding phylogeny and molecular Influenza virus epidemiology. Reassortants are not only created in the laboratory, but also in nature and then lead to the major influenza pandemics. It is general now known that the subtype H1N1 1957 of the subtype H2N2 and this again in 1968 was replaced by the subtype H3N2. Entered in 1977 then again the subtype H1N1, which is genetic largely identical to the previous one H1N1 virus was. In a genetic study, which can certainly be called classic, Scholtissek and Rott were able to show that

this The H2N2 subtype arises on the exchange several genes were based while at Subtype H3N2 essentially only the hemagglutinin Gene was exchanged and obvious originated from an animal virus (21).

Borna disease virus

Finally I would like to have a virus with - like already mentioned - very long tradition in Giessen talk, the causative agent of Borna's disease. It is a relative one rare, naturally found in horses and sheep endemic infection that presents itself as slowly progressive encephalomyelitis with regularly manifested fatal outcome. As with all slow virus infections and theirs Here, too, the experimental pathogen proved itself Access to be extremely difficult. Rudi It is Rott's great merit, along with Hermann Becht and later with Lothar Stitz and Jürgen Richt has not been here over the years Have relaxed until gradually and finally at an ever faster pace set spectacular successes. I want to try, this development here in a nutshell to trace.

The virus had long been known to be infected by its natural hosts to other animal species transmitted by intracerebral inoculation can become neurological Failure phenomena leads. On newer and especially more interesting in retrospect Aspect emerged as with Tupaias Behavioral disorders have been observed (22). The virus, which is exclusively in neuronal tissue increased by itself no signs of illness. The pathological ones Changes and clinical symptoms rather, they are the result of an immune process (23). This could clearly be seen in immune incompetent Rats are shown. Even though the virus is found in the central nervous system Animals multiplied, symptoms of disease appear only after adoptive lymphocyte transfer on. The behavioral disorders already mentioned in animals appeared in a whole new light, as Bornavirus-specific antibodies also contribute observed mentally ill people were (24, 25). In the last mentioned work first came Bornavirus-specific cDNA used. That was also for this virus the molecular age opens up, so that its gene structure then very quickly and thus its location in the system of Viruses could be cleared up.

Giessen, center of virus research

Such a large research program that I do could only sketch here in rudiments of course very clear concepts. On the scientific Concept of the multidisciplinary I have already pointed out the approach. Him faced an organizational concept Rudi caught the eye from the start and then consistently put it into practice. It consisted of all at Giessen University groups active in virology to form a research network merge, and this long before biocenters and gene centers entered the general awareness had entered. In Shape of the legendary Collaborative Research Center 47, Pathogenicity Mechanisms of Viruses, and its successor organizations then very soon suitable funding opportunities instruments found for this network. So a free space was created in which next to the already mentioned again and again new groups could unfold.

First of all, Hans Eggers should be mentioned here as the first director of the sister institute at the Medical Faculty the Verbund in its Actively supported and helped shape the beginnings.

Heinz Sänger researched viroids, self-reproducing, infectious and pathogenic RNA molecules without any envelope proteins. When in 1978 the Nucleotide sequence of the tuber spindle viroid Disease of the potato to be elucidated could, it was the first full description of the molecular Structure of a pathogen.

Gerd Wengler's group led basic Work on the structure and reproduction of Alpha and flaviviruses. These include also investigations on the West Nile virus, a Pathogen that has been found in recent times because of its rapid pace Spread to North America, where it used to be was not known, great public sensation aroused and still does.

Heinz Bauer and Bob Friis, originally also at the Schäfer's Institute in Tübingen, brought the tumor virology department to Giessen. The Group dealt with structure and multiplication of the Rous sarcoma virus and others Retroviruses, as well as in particular with the mechanisms of those indicated by these pathogens Tumorigenesis. With Wolfram Gerlich, the Heinz Bauer's successor then became scientific spectrum through hepatitis research again expanded.

When Heinz Sänger received a call to the Max Planck Institute for Biochemistry in Munich followed, Gerd Hobom was his successor the Chair of Molecular Biology. When Hobom came to Giessen, the enthusiasm jumped for the influenza viruses on him too. He became one of the fathers of the so-called here reverse genetics of influenza viruses and developed Methods used by these viruses for the first time genetically modified in an efficient way could become. You have the area revolutionized and are now relevant in all Laboratories applied.

Giessen was a center for virus research become whose charisma far beyond that Boundaries of our country. The Institute became the scientific home of many German virologists and attracted researchers from all over World for guest visits. Many became Rudis Friends for life. Personal contact was cultivated through countless evenings in the domestic circle.

Finale

Rudolf Rott has a high scientific level as a researcher Reputation acquired. His discoveries in the field of structure and Multiplication of animal viruses, especially the Influenza viruses, their evolution and pathogenesis the diseases caused by them have won numerous awards and Awards recognized by those here only the Society's Otto Warburg Medal for Biological Chemistry and the Robert Koch Prize should be mentioned. The veterinary Faculty of the Free University Berlin has given him an honorary doctorate awarded. He was an honorary member of the society for virology, which he has been doing since its inception was closely connected.

So it was inevitable that he would the scientific community in many Consulted bodies for advice. Be mentioned here only the Robert Koch Foundation, the Alexander von Humboldt Foundation and the Fritz Thyssen Foundation of which he is a member or board member served by committees. Particularly connected he felt at home with the German Research Foundation. Here he was a member of the Senate, Board of Trustees and Main Committee. Since that time the division of our country particularly linked him emotional ties to the Leopoldina. We have heard this before. The close relationships to the Max Planck Society never canceled even after leaving Tübingen. She named him hers in 1991 Member.

All these offices couldn't stop him from what he saw as his main task: for the good of his institute and for the prosperity his specialty, virology, to work. He loved the experimental work. Until the end his professional career he could in the laboratory be encountered. There he sat in the white smock buttoned on the back next to Michaela Orlich, unfortunately his too already deceased technical assistant, in order to give her, as he used to say, instructions to get how to go on should.

In 1994 Rudolf Rott retired. Jurgen Thiel, his successor, he was able to do well Institute handed over. One year old Stay at the Wissenschaftskolleg in Berlin has secured him the departure from office made easier. Our company stayed he is closely related. The evolution of virology, especially those in recent years increasingly public discussion virological He has problems with great interest tracked. His advice was asked and gladly given.

Some of the people in this room probably have Rudi with them a small symposium held on the occasion of his 75th birthday in the summer 2 years ago took place, last seen. It was admirable and moving to see like him, already badly marked by the disease, it didn't take away that listen to most of our lectures. I

would like to finish with Yoshi Nagai again Have a say on this day wrote:

> *"Rudi had many students, coworkers, and collaborators, including us from Japan. I am sure that all of them also admired Rudi as I do for his strong scientific capability and fine personality and appreciated his paternalism. They met him at a reunion to celebrate his 75th birthday in 2001, but I could not be there for a personal reason. While apologizing to Rudi for my rudeness on the phone, I learned that he had already been fighting against the disease. 'Yoshi, don't forget Gießen! 'These were his last words to me. My reply what 'Never.' "*

We all who knew him will become Rudolf Don't forget Rott. He was a great scientist a respected colleague and a good one Friend. So he becomes in our memories and stay in our hearts.

Scientific career Fields : Virology

Francis Peyton Rous ForMemRS[1] (/raʊs/) (October 5, 1879 – February 16, 1970) was an American Nobel Prize-winning virologist.

Education and early life

Rous was born in Woodlawn, Maryland in 1879 and received his B.A. and M.D. from Johns Hopkins University.[2]

Career and research

Rous was involved in the discovery of the role of viruses in the transmission of certain types of cancer. On October 13, 1966, he was awarded a Nobel Prize in Physiology or Medicine for his work.

In 1911, as a pathologist, he made his seminal observation that a malignant tumor (specifically, a sarcoma) growing on a domestic chicken could be transferred to another fowl simply by exposing the healthy bird to a cell-free filtrate.[3][4] This finding, that cancer could be transmitted by a virus (now known as the Rous sarcoma virus, a retrovirus), was widely discredited by most of the field's experts at that time. Since he was a relative newcomer, it was several years before anyone even tried to replicate his prescient results. However, some influential researchers were impressed enough to nominate him to the Nobel Committee as early as 1926 (and in many subsequent years). Rous finally received the award 40 years later at the age of 87; he remains the oldest recipient of the Nobel Prize for Medicine or Physiology.[5]

Awards and honors

In addition to the Nobel Prize, Peyton Rous was elected a Foreign Member of the Royal Society (ForMemRS) in 1940,[1] and he won the Albert Lasker Award for Basic Medical Research in 1958 and the National Medal of Science in 1965.

Personal life

In his later life he wrote biographies of [**Dr. Simon Flexner (born 1863)**] and Karl Landsteiner.[7]

His wife Marion died in 1985. His daughter Marni Hodgkin was a children's book editor, and the wife of another Nobel Prize winner, Alan Lloyd Hodgkin.[8]

Discovering the First Cancer-Causing Virus

In 1911 Peyton Rous (1879-1970) made the startling discovery that a virus could cause cancer. A farmer had brought him a hen with a large lump in her breast. Rous, a pathologist, diagnosed the lump as a sarcoma—a tumor of cells in the connective tissue. He first tested whether the tumor could be transplanted into chickens closely related to the original one. It could, and with each passing, the tumor became more aggressive. To find out whether an infectious agent caused the cancer, Rous prepared an extract—he minced a sample of the tumor tissue in saline solution and passed this through a filter to eliminate bacteria and tumor cells. Then he injected the extract into healthy chickens. Contrary to his expectations, it produced new tumors!

Describing these experiments, Rous suggested that the tumor-inducing agent was "a minute parasitic organism"—a virus. At the time Rous did this research, however, viruses were poorly understood and the causes of cancer were even more mysterious. It was more than 50 years later, in 1966, that the significance of Rous's discovery was recognized with a Nobel Prize.

The assertion that a virus could induce tumors was so controversial that, after a few more studies, Rous abandoned cancer research until the 1930s, when his colleague at the Rockefeller Institute, Richard Shope, discovered another tumor caused by a virus—a papilloma, or wart, found in rabbits. Rous returned to studying cancer, keeping alive the viral theory of cancer causation. Only in the 1950s was the so-called Rous sarcoma virus widely adopted as a tool, because—unlike chemicals or radiation—it reliably and reproducibly induced tumors. In the 1960s a gene called src was identified as producing the protein that leads to tumors. Decades after Rous's original description, the Rous sarcoma virus, now known to be a retrovirus, remains important in research.

Peyton Rous received the BA from The Johns Hopkins University in 1900, and the MD from that university's Medical School in 1905. After teaching pathology at the University of Michigan, he joined the Rockefeller Institute in 1909, becoming a full member (professor) in 1930. He remained at Rockefeller his entire career. Among dozens of awards and honorary degrees, he received the National Medal of Science (1965), the Lasker Award (1958), and the Nobel Prize (1966). He served as editor of the Journal of Experimental Medicine.

CITATION AND PRESENTATION

OF THE

ACADEMY MEDAL*

TO

F. PEYTON ROUS, M.D.

C. P. RHOADS

Director, the Sloan-Kettering Institute for Cancer Research, New York, N. Y.

As YEARS pass it becomes more frequently in order for the somewhat younger individual to speak publicly, in tribute to a somewhat older one. To perform this function a pupil of the senior is usually selected, or at least one who has some direct scientific or other reason to be indebted to the recipient of the honor. To discharge his duties properly, moreover, the payer of tribute is expected to bring forward some unique twist of phrase which will distinguish or make memorable his comment.

Until recently I have never had the honor of working with Peyton Rous, and I have no gift of words adequate to discharge properly my responsibility on this occasion. My contact with this man has been, however, of such a peculiar, and to me inspiring, nature as to lead me to acquiesce with the suggestion that I refer to it publicly, in tribute to this notable recipient of the Academy Medal.

Since it is usual and useful to refer to biographical matters, I would remind you that Dr. Rous was graduated from Johns Hopkins University in 1900, and received his medical degree in 1905. He interned at the Hopkins Hospital in medicine, became interested in pathology and continued this interest at Michigan. He was called to the Rockefeller Institute in 1909 and has been there, and a leader there, since that time.

Recall, if you will, the role of Hopkins in the revolution in medical teaching and research under way then, the inspiration given to younger men by its very great faculty, and its unique point of view.

The problem of the control of cancer disease mounts steadily

* Presented at the Annual Meeting of The New York Academy of Medicine, January 8, 1959.

F. PEYTON ROUS, M.D.

AS YEARS pass it becomes more frequently in order for the somewhat younger individual to speak publicly, in tribute to a somewvhat older one. To perform this function a pupil of the senior is usually selected, or at least one who has some direct scientific or other reason to be indebted to the recipient of the honor. To discharge his duties properly, moreover, the payer of tribute is expected to bring forward some unique twist of phrase which will distinguish or make memorable his comment.

Until recently I have never had the honor of working with Peyton Rous, and I have no gift of words adequate to discharge properly my responsibility on this occasion. My contact with this man has been, however, of such a peculiar, and to me inspiring, nature as to lead me to acquiesce with the suggestion that I refer to it publicly, in tribute to this notable recipient of the Academy Medal.

Since it is usual and useful to refer to biographical matters, I would remind you that Dr. Rous was graduated from Johns Hopkins University in 1900, and received his medical degree in 1905. He interned at the Hopkins Hospital in medicine, became interested in pathology and continued this interest at Michigan. He was called to the Rockefeller Institute in 1909 and has been there, and a leader there, since that time.

Recall, if you will, the role of Hopkins in the revolution in medical teaching and research under way then, the inspiration given to younger men by its very great faculty, and its unique point of view.

The problem of the control of cancer disease mounts steadily in importance. The major steps toward its solution have been made by a relatively small number of individuals. Among these Peyton Rous was, in 1911, one of the first. Our modern knowledge of the neoplastic process has been constructed to a large extent around his contributions.

His original demonstration of the cell-free transmission of fowl neoplasms was complete, and at the same time revolutionary. It remained a storm center of discussion among workers in cancer research for forty years. Its significance for an understanding of cancer has been fully appreciated only recently. This work remains a landmark not only in the field of its direct application, but also in virology as a whole.

But Peyton Rous saw beyond the circumscribed area of a single technique. When its possibilities were temporarily exhausted by the limited knowledge of the time, he turned, with similar skill, to other fields.

Modern hematology, replete with knowledge and procedures, gives little hint of how mysterious were the mechanisms of blood generation and destruction thirty years ago. Transfusion was a major surgical undertaking. The preservation of blood was inconceivable, its destruction little understood, and its production a mystery. "Anemia" was a diagnosis almost as useless as "fever" had been before our knowledge of the bacterial etiology of disease. Peyton Rous and his associates went far to illuminate these biological recesses.

*Immunology was also the gainer by his work. New knowledge of the source of antibodies was made available. The discovery of hydrocarbon carcinogens and of a virus-induced cancer of the mammal by [**Dr. Richard Edwin Shope (born 1901)**] brought additional new tools to hand. The complementary actions of the carcinogens and tumor viruses became a major step forward in cancer research. It contributed much to our thinking on hidden or latent viruses that may spring into action under some apparently unrelated stimulus.*

I have recounted, perhaps inadequately, some part of the formal record. May I now refer to a more personal and largely unrecorded aspect of his work. This was his contact with and influence on younger men.

As a young pathologist just entering the field of investigative medicine, I had early contact with Dr. Rous in his capacity as editor of the Journal of Experimental Medicine. I am afraid that I was a brash young man at the time, distinctly overestimating the importance of the manuscript I had submitted. In retrospect, this was not surprising since the work had no value whatever.

Dr. Rous, gravely and patiently, reviewed my efforts with me, demolished my conclusions, refuted my claims and made clear the proper use of my native tongue. He then rebuilt on the ruins such a clear picture of the problem, and the procedure required to solve it, that my conceit was converted almost imperceptibly to inspiration, my enthusiasm to resolution. As I left the generous, patient, and kindly man, I was no longer the same individual. I was, however, wholly convinced that if I worked very assiduously, with the greatest vigor, for a very long time, perhaps I could make a real contribution.

Nothing, please be assured, could have turned me then from a life in medical science.

And realize, if you will, that the world of medical research is now strongly influenced by many, many individuals, much more deserving than I, who chose that career because of Dr. Rous' unique capacity for making inspiration stick and become an irrevocable resolution.

May I then, express my deep feeling and that of many others by the following words in appreciation of Dr. Peyton Rous:

- *DETERMINATION WITHOUT DOGMATISM*
- *CONSISTENCY WITH CONSIDERATION*
- *WISDOM WITH GENEROSITY*
- *A MOST BELOVED PHYSICIAN*
- *TO WHOM SCIENCE OWES SO MUCH*
- *TO WHOM THE CHARACTER OF SCIENTISTS OWES MORE*

And may I then, Peyton, present to you the Medal of The New York Academy of Medicine, a small recognition of what you have meant to so many.

PEYTON ROUS was awarded the Nobel Prize in 1966, when he was eighty-six years old, for discoveries he had made fifty years before. He was born on the 5th of October 1879 in Baltimore, Maryland, to a family that valued humanistic education. Thus, after the death of his father, when Peyton Rous was a child, his mother rejected the idea of joining her family in Texas and stayed in Baltimore, where excellent education for the children was available. Of the two sisters of Peyton Rous, one became a musicologist, the other a painter; and Peyton himself had a flair for writing.

Peyton Rous enrolled in the Medical School of the recently created Johns Hopkins University, which he attended without special distinction. As an undergraduate he showed a naturalist's tendency and published articles about Baltimore's flowers. After graduating in medicine, he went to the University of Michigan, where he began his research career in pathology, which he perfected during a year in Dresden. In 1909 he joined the Rockefeller Institute under Simon Flexner, to engage in cancer research, against the opinion of influential friends who thought it was a hopeless field. There he remained until his death. In 1921 he became co-editor (and later editor) of the Journal for Experimental Medicine. In 1927 he was elected to the National Academy of Sciences. He died in 1970, at the age of ninety, and is survived by his wife, Marion, and three daughters, Marion, Ellen, and Phoebe.

In addition to the Nobel Prize, Peyton Rous received many honors and honorary degrees, which are listed at the end of this memoir.

The name of Peyton Rous became widely known to biologists in the fifties and sixties for his earlier discovery of a virus causing sarcoma in chickens, which became aptly known as the Rous Sarcoma Virus. At the time he became famous, Peyton Rous appeared as an elderly, highly educated, gentleman with silvery hair. But in his youth he was a very hardworking scientist with a determined, fiery, and highly critical personality. He was a medical man who wished to learn about cancer as a disease and a biologist who did not want to follow the beaten track, and he was willing to hunt for new clues in well-designed but slow experiments.

I, like most of my contemporaries, became acquainted with Peyton Rous's fundamental discovery in the early fifties, when Harry Rubin came to my lab to work with the Rous Sarcoma Virus. He started using a focus technique on the chorioallantoic membrane of the chicken embryo, which Rous had invented many years before. **Later I had occasion to meet Peyton Rous several times on the platform as a speaker, or across the discussion table, or in his laboratory at the (then) Rockefeller Institute. I remember the man-rather small in stature with silvery hair and penetrating eyes. I also remember that before our first meeting I was inclined to think of him as a figure of the past, but soon changed my mind at that meeting and even more so at subsequent ones. Clearly, he was very much alive until his very last days, with a keen interest in new developments in virology and cancer research. He was able to discuss his past work with equanimity and to accept new interpretations of his data. I remember I suggested to him an explanation of the clonal characteristic of the neoplastic transformation of papillomas in terms of somatic cell genetics, a concept that was not part of cancer research in the period of his active work. His interest was immediately aroused; he asked me for a thorough clarification of what I meant and then argued, with passion but no animosity. We parted like old friends who have found something new to talk about. At the time when phage lysogeny was the domain of a very small group of virologists, I suggested to him that it might represent a good model for some features of viral cancer. Again his interest was acute, and I had to embark on a detailed discussion of phage integration, immunity, and lysogenic conversion.**

Peyton Rous discovered the viral etiology of a chicken sarcoma in 1911 through his interest in tumor transplantability to new hosts by a filtrate. He commented: "The behaviour of the new growth has been throughout that of a true neoplasm, for which reason the fact of its transmission by means of a cell-free filtrate assumes exceptional importance" (1911).

He fully realized from the outset that this was "a unique and significant finding" (191 1). He also realized that the significance of the discovery depended on

the true nature of the induced growth. As an experienced pathologist he could see that it was a true cancer: "The (pathological) picture (of the growth) does not in the least suggest a granuloma . . . it exhibits to a special degree, not merely a few, but all those features by which the malignant neoplasms are characterized" (1911).

For about forty years this momentous discovery had little impact, because the minds of scientists were not prepared to think of viruses as agents of cancer. It was expedient to say that the chicken tumor was not a cancer, but some kind of reaction to the virus more akin to inflammation than neoplasia, and perhaps a peculiarity of chicken biology. Peyton Rous soon recognized himself that the tumor would not be accepted as a cancer because it was transmitted by a cell-free extract: "A passing reference should perhaps be made to the ill-defined group of pathological products called granulomata, with which this neoplasm of the fowl may by some be classed, owing to its transmission by an agent separable from the tissue cells" (191 1). Many years later he wrote, "This disclosure (that certain chicken tumors were proved due to viruses), which conflicted with the negative findings in mammalian growths, was determined forthwith as erroneous" (1952).

One wonders how firmly in the early years Peyton Rous himself was convinced that he had demonstrated the induction of a cancer by viruses. The statements he made at the time are very cautious and full of qualifications. At first he used to refer to the "agent" that induced the sarcoma; but a year later, after he discovered a new, different tumor transmissible by filtrate, he proposed that the "agent is probably a living virus" (1912).

During the years 191 1-1914, Peyton Rous worked hard at disproving the objections on the nature of the induced tumors by isolating other viruses that induced tumors in chickens and by carefully studying their pathology. He could show that the tumors induced by the different viruses were capable of invading neighboring tissues and of metastasizing to distant organs; thus they were true cancers. Moreover, each independently isolated virus caused a tumor of a different kind. These facts should have been convincing evidence that the growths were specific responses of the host, yet this conclusion was not generally accepted. However, these discoveries seem to have been convincing for Rous, who wrote, "The findings with the chicken tumors largely demolish the theoretical basis in which objections to an extrinsic cause for cancer have been built up" (1912).

In order to find more generally acceptable evidence, Peyton Rous attempted to extend his observations "especially through carefully devised experiments with the tumors of other species of animals" (1911). Evidently for the viral etiology to be accepted, similar findings were needed in mammals. The strategy of Rous's future work was determined at that time. However, the extension to other species came only many years later with Richard Shope's discovery of the rabbit papilloma virus.

In the meantime Peyton Rous studied many features of the cell-free transmission of the tumor. Examining the effect of the age of the host, he showed that the virus induces characteristic foci on the chorioallantoic membrane of the chicken embryo. This result supplied an assay for the virus that was universally employed until the fifties, when it was superseded by the focus formation in tissue culture.

In this extensive and careful work, Peyton Rous observed the host resistance to the transmission of the tumor, in the form of either absence of growth, slow growth, or normal growth followed by regression. Other experiments showed how essential the conditions of the host are for the development of a tumor after inoculation of the virus. From this observation Peyton Rous began to recognize the existence of limitations to the expression of the oncogenic potential of the virus: "How does it happen that the sarcoma, though ultimately dependent on an extrinsic agent, is dominated in its behaviour by the cells composing it?" (1912). Perhaps the agent depends "on a special set of conditions in order that it might produce a neoplastic change" (1912). He returned later to this point on several occasions.

After discovering the second chicken tumor agent, Peyton Rous started wondering about the etiology of cancer in general: "The demonstration that extrinsic agents are the cause of two connective-tissue growths of the fowl which are characteristic malignant tumors renders it necessary to suppose either that such tumors of the fowl have an entirely different etiology from mammalian tumors, or else that the latter are of similar origin" (1912). This point was also developed to a much greater extent later on.

As further evidence for a viral nature of the chicken tumors, the resistance of the host to the tumor cells could be separated from its resistance to the tumor-inducing agent. Moreover, Rous discovered a third chicken tumor, transmissible by filtrate, markedly different in properties from the two previously described: "The findings with the three tumor-producing agents have a striking similarity and it is difficult to avoid the conclusion that the three are of one class, whatever that class may be. . . . It is perhaps not too much to say that their recognition points to the existence of a new group of entities which cause in chickens neoplasms of diverse characters" (1914).

At the beginning of World War I, Peyton Rous, under the pressure of wartime medical needs, gave up his work with chicken tumor viruses. For the following twenty years until 1934, his interest was in the fields of blood transfusion and attending immune reactions, liver and biliary functions, cellular functions, and vascular permeability. I will return to these activities later on.

A turning point in Peyton Rous's work on cancer was the discovery of the Shope papilloma. In 1933 Richard Shope reported his discovery that a mammalian tumor, the papilloma of cottontail rabbits, was transmitted by a virus-like agent. As in the case of the chicken tumor, Peyton Rous's first concern was whether the papilloma was a true neoplasm. He decided that it was, because, when the papillomas were transplanted deep inside the body, they developed into carcinomas that grew invasively and killed the host. Furthermore, in domestic rabbits the virus-induced papillomas often grew progressively, invading the neighboring tissues and producing metastases, and this malignant evolution could be enhanced by exposing the papillomas to various substances, such as Scarlet Red.

These findings seem to have been for Rous the decisive argument for the validity of his conclusions concerning the chicken tumors, since in a mammal cancer could also be transmitted by a virus. He, therefore, returned to the study of carcinogenesis using the papilloma virus as a new tool. He focused at first on the malignant evolution of the papillomas. By careful observations, following small hints, such as the shape of their growths, color, or the degree of pigmentation, he showed that a few cells in a papilloma became cancerous and generated clones, each with different characteristics.

In trying to understand how such evolution to cancer occurs, Peyton Rous studied the effects of tar, as both a carcinogen and tumor promoter. He found that tar not only strongly enhanced the induction of papillomas or carcinomas by the Shope virus in domestic rabbits but by itself elicited similar papillomas. Could tar papillomas also be virus-induced?

This new phase of Peyton Rous's work, although a natural development of his earlier work, had more ambitious goals, for it aimed at testing the hypothesis that "this disease (cancer) is an infection. . . . A main attraction of this hypothesis is its accessibility to test." However, he clearly saw that this hypothesis could only be true under certain conditions, one of which is that "a living entity responsible for such growths must require for effectiveness a very special basis of predisposition" (1932). He sought to possibly disprove the infectious nature of cancer by comparing the frequency of cancer induction by tar in the skin of two groups of mice with different exposure to the environment: "The animals of one group have been placed under conditions which would facilitate

the entrance into the body of extraneous living agents, whereas those of the others have been sedulously protected" (1932). The results proved "that the mouse cancer cannot be caused by living entities reaching the body from the surrounding world during adult life" but "fail to exclude the possible activity of entities residing habitually in or upon the body" (1932). This experiment showed another requirement of the hypothesis on the infectious nature of cancer: "The supposition (that tumors in general are due to viruses or other extraneous entities) is tenable only if such entities are widely distributed throughout the animal population, being constantly present in or upon the body, like the colon bacillus or the staphylococcus; and if their opportunity to cause tumors is restricted by the need for very special conditions. . . . The more considerable an agent is conditioned in its activity, the more often must it be present if it is to cause disease at all" (1934). These words were prophetic, as shown by the recent developments in the field; yet they were simply the result of cool, logical assessment of the facts then in hand. However, for Peyton Rous this hypothesis was only a guide for the experiment: "The demonstration of the cause for the generality of tumors, whatever this is, waits upon the provision by the investigator of the conditions necessary to its effectiveness" (1934).

He tried several new approaches. One of the major tools was still the technique of inducing skin tumors by application of tar. He used it to create favorable cellular conditions for revealing the neoplastic potential of viral agents. Another tool was the immunity of the infected rabbits against the Shope virus. Peyton Rous found no demonstrable antibodies in rabbits without papillomas or in those with tar papillomas or Brown-Pierce tumors: these findings "speak decisively against the possibility that these growths are caused by viruses antigenically related to the one causing papillomas. Yet this does not exclude a virus causation for them, since the sera of fowls with Chicken Tumor I and Fujinami Sarcoma respectively, though possessed of neutralizing power for the virus causing the growth carried by the host, have no cross-neutralizing effect whatsoever" (1936).

Shortly afterwards, in taking a bird's eye view of his past work and of the cancer problem, he concluded: "How far should one be led by the assumption that certain tumors may be due to viruses? Only so far as to make tests with these growths. The tumor problem has withstood the most corrosive reasoning. Yet since what one thinks determines what one does in cancer research, as in all else, it is as well to think something. And it may prove worthwhile to think that one or more tumors of unknown causes are due to viruses" (1936). He thus recognized that the problem that he so clearly formulated and actively pursued eluded experimental attack and remained unsolved. In fact he later restated the basic question: "What is the papilloma doing in the cancer, if anything?" (1940).

In a renewed effort to answer this question, Peyton Rous used as a new tool the famous line of transplantable rabbit cancers, derived from a viral papilloma called at first "carcinoma V2" (1940), and then, after World War 11, V x 2 because during the war V2 "came to have another significance" (1952). This line did not contain infectious papilloma virus, but for many serial transfers in rabbit it continued to elicit the production of virus-specific antibody.

The result suggested that the virus may play a determining role although in "masked or altered form" (1940). This was a new idea in virology, which had enormous developments many years later. For the next three years, during serial transplantation from one rabbit to another, the V x 2 carcinoma continued to elicit this immune response. However, when it was retested after an interval of one and a half years, four and a half years after its origin, the tumor was found unable to immunize against the papilloma virus; the loss of this property "was not attended by any perceptible change in the V x 2 carcinoma" (1952). This "wholly unexpected" result must have been quite shattering; and Peyton Rous was led to rethink the role of the virus in the production of the cancer. In this agonizing reappraisal he proposed that the virus might have undergone "wider variation" (1952); but he recognized that "at this uncertain point the problem of the cause for the V x 2 carcinoma must perforce be left" (1952). In this way the work of Peyton Rous went full circle: from complete ignorance on the role of viruses in cancer to definitely establishing such a role through brilliant discoveries, to postulating a wider and possibly general role of viruses in spontaneous cancers, and ending up again in a condition of uncertainty. I should not say full circle, but rather one turn of the helix, because the uncertainty was now of a different kind.

The emphasis of Peyton Rous's work in the forties and fifties shifted from the viruses to chemical carcinogens. Many articles were dedicated to the potentiating effect of tar and other carcinogens on virus-induced papillomas. During this work it also became clear that tar alone induces papillomas very similar to those induced by the virus on normal skin or on skin pretreated by tar. In all cases the growth showed progression, i.e., remained benign for some time and then developed into carcinomas, which arose in a few isolated cells. However, many observations also showed that the role of the virus and of the chemicals was different: "The generality of the carcinogens bring about tissue conditions out of which tumors may or may not arise for reasons still undetermined. They may'be fitly called provocative carcinogens. The viruses, on the other hand, both initiate tumors and determine their character and behaviour. They are actuating carcinogens" (1943).

In a new series of experiments, Peyton Rous convincingly demonstrated that the viral and the chemical agents have a cooperative action, producing in combination cancers at much higher frequency and after shorter time than either agent alone. On the basis of this cooperation, Peyton Rous made three important suggestions. One bears on the mechanism of carcinogenesis. He proposed that in utero or at a young age the human or animal body becomes invaded by viruses that "would give no sign of their presence in most instances. . . . But if a provocative carcinogen happened to work on the cells with which such a virus was associated . . . it might undergo variation and . . . give rise to a tumor. The new pathogenic variant would not be transmitted to other animals . . . but would be a dead-end virus, though the harmless source virus liable to the same or other variation would be passed on" (1943). This hypothesis is very similar to some prevalent at the time of this writing, if the dead-end variant is interpreted as a defective integrated provirus that has incorporated a silent oncogene, causing its expression.

Another suggestion was that chemical carcinogens might cause the so-called spontaneous tumors. He added, "A list of human tumors which have been traced to the action of provocative carcinogens is in no small degree a sociological document, reflecting as it does the ways of life, vocation, avocations, habits and environmental stresses of people and individuals" (1943).

The third suggestion was that viruses and chemicals in combination might have a continued role in spontaneous cancer: "The recent discovery that viruses of some sorts lie latent for long periods, causing disease only on special occasion, coupled with the realization that some tumors have viruses as their cause, has led to a supposition already mentioned that agents of this sort may reside in animal tissues, perhaps throughout the lifetime of the organism, doing no harm unless the cells with which they are associated undergo special pathological changes, when they undergo variation as a result of the new, abnormal milieu and render the cells neoplastic. According to this supposition, tar and methylcholanthrene are carcinogens because they alter the environment of viruses. . . ." (1944). Such a possibility is very much in the minds of virologists and oncologists today.

During his work on carcinogenic hydrocarbons, Peyton Rous identified important features of the neoplastic process they initiate. One is that their cancer-inducing activity is greatly enhanced by promoters that stimulate cell proliferation, for instance, wounds. Another feature is that "cancers arise by a step-like progression" (1941). Peyton Rous recognized the importance of this observation, because "the cells of not a few tumors attain to their worst by further neoplastic changes which are scarcely less significant than the one primarily responsible for their state. Indeed the practical significance of these changes is often greater as meaning death to the patient" (1955).

In his later years Peyton Rous continued his experimental work, but his contributions declined in number and relevance. During that time tremendous

changes were occurring in biology, especially the great development of genetics and the birth of molecular biology. Although Peyton Rous showed great interest in these developments, he failed to assimilate them. Obviously, even a brilliant mind is subject to the limitations of age. He became attached to old concepts. The main consequence was his rejection of somatic mutations as a possible cause of cancer and his failure to recognize viruses as new genetic material in the cells they infect. It may be said about him what he said about Leo Loeb: "He outlived his era of discoveries about cancer but what he did for science endures" (1960).

The work on cancer is the big basis on which Peyton Rous's fame rests. The other work, which I already mentioned, is permeated by a similar perceptiveness, imagination, and experimental ability. I should mention especially the work on blood preservation and substitutes, which Peyton Rous carried out during World War I, because it shows another facet of his personality, i.e., the ability to respond to urgent medical needs of society. For instance, in 1918 he wrote: "There exists at present a great and urgent need for an injection fluid that can be satisfactorily employed instead of blood for transfusion in cases of hemorrhage. It is common knowledge that casualty clearing stations, after a 'push', are crowded with men who have lost too much blood to be operated on, who cannot be revived by means of salt solutions and supportive measures, but who would undoubtedly respond to transfusion. For the latter neither time nor donors are available." Quite rapidly, at the beginning of the war, Peyton Rous and associates perfected a method for storing human red blood cells, using a weak gelatin solution to protect them during washing and sugars to preserve them. The procedure was used to establish the first blood bank during the war, which was operated by one of Rous's collaborators. And the solution for suspending the red cells, known as the Rous-Turner solution, is still in use. Such an accomplishment would be a sufficient reason for fame, because it has both scientific and humane values. We know that Peyton Rous was very proud of it.

In addition to his experimental work, Peyton Rous had another absorbing interest: the editorship of the Journal of Experimental Medicine. It is known that he dedicated to it an immense amount of time and energy. He was reputed for the accuracy of his editing, both in regard to scientific content and style. I well remember when I, as a prospective author, first encountered him as an editor. He returned my manuscript with many remarks, mostly of style. I remember I was at first baffled, but then, after studying his comments further, came to appreciate their reasons, which went beyond the mere words. I realized that for him a word, every word, was a concept, which should be examined not only in its present, but also future, context. He reminded me in his letter that I should think that a certain word might become widely adopted and that I should therefore choose it with deliberate care. He was anticipating the flooding of scientific literature with laboratory slang, which has happened in recent times and which was a trend of which he strongly disapproved. But during his editorship, he succeeded in maintaining the Jozirnal of Experimental Medicine at a high level, both in purity of language and strength of content.

Peyton Rous remains in the minds of those who knew him, especially the younger generation, as the image of a man fully dedicated to his work, a scientist with vision, a strong although kind person, with a good sense of humor. His experiments were always designed to test hypotheses and developed in a logical sequence on the basis of results already secured; they were very methodical and thorough and were reported in detail with extreme clarity. He was independent in thought and was against conventional beliefs unsubstantiated by evidence. For instance, he commented:

"Not so long ago in the dark ages of medicine, one could think nearly anything about disease because one knew almost nothing. Theoretical system succeeded system, from humours to homeopathy. Opinions strongly held appeared like realities and were acted upon as such. Now for most diseases all this is at an end: fact has killed fancy. . . . The tumor problem is the last stronghold of metaphysics in medicine" (1936).

Although during his career he formulated some penetrating hypotheses not amenable to direct test, he was fundamentally interested in facts: "No explanation of the cause of cancer is worthy of attention that cannot be tested" (1932).

The language of his reports was vivid, full of images from everyday life, as shown by a few examples:

"The fowl limps and its wings seem stiff" (1913).

"The growth gives it (the fowl) a factitious plumpness" (1913).

"During the outward extension of the membrane (of the Kupffer cells), lava-like flows can be seen on its surface, when the light is cut down, and at its edges fimbriated or 'petaloid' extrusions, at times appearing whip-like, which are in constant slow motion" (1934).

Comparing his work with the chicken viruses, which started with a cancer and led to a virus, and with the Shope virus, which started with a virus and led to a cancer: "The trails have met at the same look-out. What does one see from this?" (1936).

His humor was sometimes biting: Speaking of new reactions elicited in the human body by surgery, he saw their positive aspects: "All that surgery has done in such instances is to make plain the relation of effect to cause, as for example in showing that tetanus is due to insufficiency of the parathyroids, and myoxedema to a thyroid lack" (1929).

The most visible side of Peyton Rous was his interest in scientific truth, in the younger people, the equanimity of judgment and the warmth of human relations he was able to establish both inside his family and outside. I had a hint of this when recently his daughter, Marion, referred to him as "daddy" in an affectionate way; and when several years ago he wrote to me sending his congratulations for the Ehrlich Darmstaedter award (which he nominated me for) and suggesting the nicest Ratskeller in Frankfurt, with the best food, wine, and atmosphere.

Peyton Rous received many official honors in his life, including the highest. But the paramount recognition was the admiration and respect of his younger colleagues, which continues after his death.

Rous and Rhoads association : Yes ... / PDF : [HP005P][GDrive]

Francis Peyton Rous

Prasanna Kumar and Frederick A. Murphy

This is a photograph of Peyton Rous (Francis Peyton Rous, 1879–1970), who in 1909–11 made 2 seminal discoveries that are now the foundation blocks of modern virology and oncology. First, he discovered that a malignant tumor (a sarcoma in chickens) was transmissible; this was the first transmissible solid tumor discovered. Second, he found that the tumor-inducing factor could be passed through a Berkefeld ultrafilter known to retain bacteria. In the context of the times, this finding proved that the agent was a virus, the first of its kind. The virus he discovered is now known as Rous sarcoma virus and has since been studied in many laboratories around the world.

Rous was born in 1879 in Baltimore, Maryland, USA, and raised by his widowed mother, who persevered in supporting his education. He received bachelor of arts and doctoral degrees from The Johns Hopkins University in Baltimore in 1900 and 1905, respectively. After teaching pathology at the University of Michigan, Ann Arbor, and studying morbid anatomy at Friedrichstadt Municipal Hospital in Dresden, Germany, in 1909, he took a position at the Rockefeller Institute for Medical Research in New York, New York, where he spent the rest of his life. Rockefeller was the place in the United States where virology first emerged as a distinct medical science; from the beginning of his career, Rous was surrounded by great scientists.

Rous' entry into tumor virology was fortuitous; the founding director of the Rockefeller Institute, Simon Flexner, had been interested in oncology but wanted to redirect his own work toward polio, which was becoming a major problem. Rous was hired to continue Flexner's research into oncology, a subject about which Rous at first knew nothing.

The beginning of the story behind Rous' claim to fame is remarkable: a woman came to the Rockefeller Institute with a barred Plymouth Rock hen that had a large tumor on its breast. Rous later wrote, "In this paper is reported the first avian tumor that has proved transplantable to other individuals. It is a spindle-celled sarcoma of a hen, which has thus far been propagated to the fourth generation…." In his research, he found that only closely related chickens were susceptible, but in these chickens, continuous passage of cell-free material led to tumors that grew quickly, were more malignant than usual, and produced widespread metastases. Rous continued to study the phenomenon he had begun to unravel for many years, but understanding the mechanistic bases for the complex natural history of Rous sarcoma virus and related viruses had to wait until modern molecular and cellular biologic technologies became available in the 1960s.

In 1934, Rous' Rockefeller Institute colleague, Richard E. Shope, asked him to examine warts on jackrabbits that had definitively been shown to be caused by an

This is a photograph of Peyton Rous (Francis Peyton Rous, 1879–1970), who in 1909–11 made 2 seminal discoveries that are now the foundation blocks of modern virology and oncology. First, he discovered that a malignant tumor (a sarcoma in chickens) was transmissible; this was the first transmissible solid tumor discovered. Second, he found that the tumor-inducing factor could be passed through a Berkefeld ultrafilter known to retain bacteria. In the context of the times, this finding proved that the agent was a virus, the first of its kind. The virus he discovered is now known as Rous sarcoma virus and has since been studied in many laboratories around the world.

Rous was born in 1879 in Baltimore, Maryland, USA, and raised by his widowed mother, who persevered in supporting his education. He received bachelor of arts and doctoral degrees from The Johns Hopkins University in Baltimore in 1900 and 1905, respectively. After teaching pathology at the University of Michigan, Ann Arbor, and studying morbid anatomy at Friedrichstadt Municipal Hospital in Dresden, Germany, in 1909, he took a position at the Rockefeller Institute for Medical Research in New York, New York, where he spent the rest of his life. Rockefeller was the place in the United States where virology first emerged as a distinct medical science; from the beginning of his career, Rous was surrounded by great scientists.

Rous' entry into tumor virology was fortuitous; the founding director of the Rockefeller Institute, [**Dr. Simon Flexner (born 1863)**], had been interested in oncology but wanted to redirect his own work toward polio, which was becoming a major problem. Rous was hired to continue Flexner's research into oncology, a subject about which Rous at first knew nothing.

The beginning of the story behind Rous' claim to fame is remarkable: a woman came to the Rockefeller Institute with a barred Plymouth Rock hen that had a large tumor on its breast. Rous later wrote, "In this paper is reported the first avian tumor that has proved transplantable to other individuals It is a spindle-celled sarcoma of a hen, which has thus far been propagated to the fourth generation…." In his research, he found that only closely related chickens were susceptible, but in these chickens, continuous passage of cell-free material led to tumors that grew quickly, were more malignant than usual, and produced widespread metastases. Rous continued to study the phenomenon he had begun to unravel for many years, but understanding the mechanistic bases for the complex natural history of Rous sarcoma virus and related viruses had to wait until modern molecular and cellular biologic technologies became available in the 1960s.

In 1934, Rous' Rockefeller Institute colleague, [**Dr. Richard Edwin Shope (born 1901)**], asked him to examine warts on jackrabbits that had definitively been shown to be caused by an ultrafilterable virus. This virus was Shope papillomavirus (rabbit papillomavirus). When Rous confirmed that the warts were benign tumors, he was reinvigorated in his intent to unravel the mysteries of viral oncology. Over the next 30 years, Rous and his colleagues showed that the benign tumors could progress to malignant carcinomas and that chemical carcinogens could interact with the virus— further discoveries that formed building blocks for modern virology. Today, we recognize that ≈20% of human cancers worldwide have infectious etiologies, for which preventive measures such as vaccines have great promise.

Rous' colleagues, including the scientists René Dubos and Charles B. Huggins, lauded Rous' personal and professional qualities, writing that he was gifted with supreme intellectual powers, unfailing integrity and honesty, a remarkably intuitive sense for the science itself, great perseverance and work ethic, and an enormous zest for life. One can imagine with wonder Rous in his laboratory and in the legendary lunchroom of the Rockefeller Institute.

Rous was duly honored for his masterful work, winning the National Medal of Science and membership in the National Academy of Sciences, the American Philosophical Society, the Royal Society, and other prestigious organization.

In 1966, when he was 87 years old, Rous was awarded the Nobel Prize in Medicine, an honor he shared with Charles Huggins. After 55 years, the longest "incubation period" in the history of the Nobel Prizes, Rous' discovery had finally been recognized with this honor. In the end, proof that Rous was just ahead of his time might be found in the several additional Nobel Prizes awarded since 1966 to virologists who further unraveled viral oncology Control and Prevention, Atlanta, Georgia. He is planning on a career in medicine.

Dr Murphy is a professor at the University of Texas Medical Branch in Galveston. Formerly, he was chief of the Viral Pathology Branch, then director of the Division of Viral and Rickettsial Diseases, and then director of the National Center for Infectious Diseases at the Centers for Disease Control and Prevention.

Francis William Ruscetti (born 1943)

Birthday - Feb 6 1943 (See [HL003Z][GDrive])

Worked at Litton Bionetics

Mentor of Dr. Judy Anne Mikovits (born 1958)

https://www.courtlistener.com/pdf/2017/09/27/rogero_v._secretary_of_health_and_human_services.pdf

Dr. Ruscetti received his B.S. in Biology in 1968 from Boston University, and his Ph.D. in Microbiology from the University of Pittsburgh in 1972. (Ex. 238, p. 1.) From 1972 to 1975, Dr. Ruscetti was a Research Instructor at the University of Pittsburgh, School of Medicine. (Id.) From 1975 to 1978, Dr. Ruscetti worked for a private company, and since 1978, has held various senior positions at the National Cancer Institute (NCI). (Id., pp. 1-2.) He currently serves as the Principal Investigator for NCI's Leukocyte Biology Section, and has been an Adjunct Professor of Biochemistry and Molecular Biology at George Washington University -- a position he has held since 1988. (Id.)

Dr. Ruscetti has co-authored more than 300 scientific publications, served on editorial boards of several scientific journals and is currently on the editorial board for Stem Cells. (Ex. 238, pp. 2-32.)

As discussed above, although Drs. Ruscetti and Mikovits are said to have co-authored an expert report (Ex. 236), Dr. Ruscetti did not testify at the evidentiary hearing.

Ruscettis Take Trip To Aruba

A wedding trip to Aruba followed the ceremony for Sandra Kay Ickes and Francis William Ruscetti in the First Unitarian Church. The Rev. Jesse Cavileer officiated on April 25. A reception followed at the Fairfax. The couple plans to live in Pittsburgh.

Both are working toward their doctorates at the University of Pittsburgh. She is a graduate of Ohio University and he, of Boston University.

The bride, daughter of Mr. and Mrs. Raymond Ickes of Steubenville, asked Linda Ickes, to be maid of honor. Jane Arista and Judith Trubilla were bridesmaids.

Mr. Ruscetti, son of Mr. and Mrs. Frank Ruscetti of Boston, asked Robert Ruscetti, to be best man. Roy Englebrecht and Roger Weppelman were ushers.

New hope in leukemia research

By VICTOR COHN
Washington Post

WASHINGTON — What may be a human leukemia virus has been isolated by National Cancer Institute scientists.

The discovery, one they call "exciting" and other authorities call "highly significant," could trigger new interest in searching for viruses as causes of human cancer.

It could also lead to new ways of treatment and even prevention, though it is far too early to say what might or might not be possible.

Dr. Robert Gallo, chief of NCI's Laboratory of Tumor Cell Biology, and his co-workers have so far found the virus in four patients as well as antibodies to the virus — solid evidence of the body's effort to resist it — in 12 more.

Japanese doctors at the University of Kyoto, collaborating with Gallo, reported last week that they too have begun to find the virus in some patients.

Viruses cause cancers without a doubt in several animal species. And they cause leukemia — blood cell cancer — in cows, cats, mice and chickens, as well as gibbon apes, close relatives of man.

But scientists have looked for human cancer viruses for decades with generally thin results. Viruses have been at least "associated" with three human cancers, "associated" meaning they are somehow involved in the cause, with other factors. The three are liver cancer, cancer of the cervix and oned NCI, part of the government's National Institutes of Health, has been criticized for spending too much money on virus research.

Gallo's discovery "gives a strong stimulus to reopen investigations into viral involvement" in human leukemias, Dr. William Jarrett of the University of Glasgow has told Oncology Times,a publication for cancer researchers.

(Continued on page 5)

Leukemia (Continued from page 1)

Gallo's main colleagues in this work have been Bernard Poiesz, Marvin Reitz Jr., Francis Ruscetti, V.S. Kalyanaraman, Marjorie Guroff and M. Sarangadharan.

"What we have found," he said in an interview, "is a new retrovirus or RNA virus." RNA and DNA are nature's two main kinds of genetic material.

Retroviruses cause the known animal leukemias. The one that causes cattle leukemia, a disease highly destructive to livestock, is at least distantly related to the new NCI virus.

Retroviruses are also of high interest today in biology.

It is known that they sometimes carry so-called transforming genes into cells. These may promote normal growth or, sometimes, lead to cancer — either by inserting their new information wrongly or by turning on another gene that makes cells grow inappropriately.

Until now, says Dr. David Baltimore, Massachusetts Institute of Technology Nobel prize-winner, the lack of any known human retrovirus has been a major gap, "so even if this virus is just a human virus and causes no known disease, it is important."

Gallo too says, "We can't yet say this virus causes a leukemia." But he also says, "We clearly are getting an association of this virus with a form of leukemia," and though "we can't say yet that it is an etiologic agent, we suspect it."

He has at least provisionally named the virus "HTLV" for "human T-cell leukemia-lymphoma virus" — "T-cell" because this is the kind of white blood cell that proliferates in this kind of leukemia.

ONE OF THE MAIN problems, always, in studying leukemias and lymphomas — lymph gland cancers, closely related to the leukemias — has been getting T-cells to grow in the laboratory.

Six years ago Gallo, Doris Morgan and Ruscetti found a protein they call TCGF for "T-cell growth factor." This has proved to be the magic key to growing T-cells and leukemia and lymphoma cells well and reliably.

It is this technique that has enabled the NCI group to isolate and grow HTLV virus from four patients with an unusual "and very aggressive" leukemia or lymphoma that often closely resembles a disease called "Sezary leukemia."

Because isolating and growing a virus from any one patient is still long and laborious work, the scientists have screened blood samples from many other patients and found 12 with anti-HTLV antibodies. They have shown there are no such antibodies in the blood of 200 healthy persons.

ANTIBODIES ARE proteins the body makes to fight harmful aggressors. "They are flags that tell us where the virus has been," Gallo explained.

Now, he said, there must be much more study, including epidemiological surveys to see how widespread the virus may be. This will include collaboration with Japanese doctors, since a closely related or perhaps the same form of leukemia is found in a kind of cluster in southwest Japan, and blood samples from Japanese patients have revealed telltale antibodies to the NCI virus.

The Gallo evidence, says Dr. David Katz of the Scripps Clinic and Research Foundation is "quite impressive and convincing." But, says Dr. Max Essex of Harvard, it is going to be a slow process at best to firmly prove this or almost any new-found virus causes human cancer.

GALLO IN 1975 felt sure he had isolated a leukemia virus, but was unable to prove it. What he feels "99 per cent sure of today," he said, is that he just "couldn't keep the virus growing then" and it was replaced in his lab cultures by a contaminant, a primate leukemia virus.

How do people get the new-found virus, if it is indeed a leukemia virus?

"We don't know," he said. "We don't think it, or any cancer, is infectious in the common way, like a cold. There may be infection at a very low level, probably only in genetically susceptible individuals.

"We can speculate, however, that this virus sometimes reaches humans from someplace outside them. You're not born with it in your genes. Then, in some susceptible people, it replicates." That is, it grows.

And in persons whose cells permit such growth it may unlock a gene that starts another step, or whole series of steps, that may lead to a cancer in a process still only dimly understood by inquiring scientists.

ETIOLOGY OF MYELOID STEM CELL DISEASES

F.W. Ruscetti

INTRODUCTION

The existence of a common etiologic agent for such a heterogeneous group of diseases as those that reflect clonal neoplasms of this cellular system is unlikely. Cellular transformation should be divided into at least two distinct phases. The first phase is the primary lesion or "initiating event" which is produced by the etiologic agent(s). It is safe to say that almost nothing is known about these changes in stem cells. The second phase involves the changes that are necessary for maintaining growth of the abnormal cell once transformation has occurred. These changes can occur either as a result of mutational (genotypic) changes in the cell itself or from alterations in secondary cells important in cell regulation, which cause a phenotypic change in the transformed cell. The following are possible etiologic agents:

Viruses

Viruses are the primary suspects as causative agents of these human neoplasms and this suspicion is based primarily upon data derived from studies in lower mammals.

Laboratory-Derived Acutely Transforming Viruses

Unlike viral-induced naturally occurring neoplasia, these "laboratory" viruses induce a fulminating leukemia in 4 to 6 weeks in susceptible animals. Friend leukemia virus, a prototype of this group, unequivocally interacts and directly transforms the myeloid stem cell. The following observations and developments have led to greater understanding of these agents: 1) development of systems for the transformation of myeloid stem cells in vitro; 2) strongly oncogenic viruses differ little in molecular terms from nononcogenic viruses of the same type; 3) viral transforming sequences are closely related to the DNA in normal cells; and 4) oncogenic viruses have been shown to be a result of recombination.

Further study of these agents should prove quite valuable. For example, this group of viruses is easily the most useful in describing the primary initiating events in cellular and molecular terms, and if there is one common unifying mechanism in stem cell transformation, it is most likely to be a permanent genetic change caused by the initiating event.

Research Needs

* Molecular cloning of transforming information
* Development of transforming fragments through restriction endonuclease mapping
* Further development of assays for transformation in vitro.

Digitized by Google

[HG004R][GDrive]

Naturally Occurring Oncogenic Viruses

In every case where the primary etiology of naturally occurring leukemias of animals is known, (such as in chickens, cats, Gibbon apes, and cows) an acquired RNA tumor virus is involved. The mechanism of transmission, vertical or horizontal, is usually known, but the mechanism of actual cell transformation is not. Thus, among the major areas of fruitful study are the determination of whether these viruses acutely transform or indirectly stimulate transformation; and the development of further animal models for human disease, such as Feline leukemia virus, which induces aplastic anemia and myelofibrosis, and Gibbon ape leukemia virus, which induces a CML-like disease.

Viruses in Man

Information here is still quite incomplete in comparison to other animals but can be summarized as follows. 1) Type C viral information: certain reported viruses are indistinguishable from known primate viruses and are likely to be contaminants in vivo or in vitro. 2) Herpes viruses: association of herpes simplex with cervical cancer and Epstein-Barr virus with Burkitt's lymphoma is interesting but not conclusive with respect to cause and effect. 3) Recently described is a candidate oncornavirus, which has been associated with mycosis fungoides-Sézary syndrome in the United States and a perhaps similar virus associated with T cell leukemia in southern Japan.

Research Needs

* Searches for viral agents in man should be concentrated on the most likely malignancies to have a viral etiology, such as Hodgkin's disease and other lymphoreticular diseases.

* There is no doubt that hematopoietic stem cells are extremely sensitive to genetic damage by chemicals, radiation, and other environmental influences. Better assay systems for measuring the carcinogenic potential of chemicals are needed, (although all that might be accomplished from a "practical view" could be the expansion of an already lengthy list of chemicals which are known to be harmful to man.)

* A variety of genetic diseases are associated with a high frequency of transformation, leading to clonal neoplasms. These include several syndromes associated with chromosomal abnormalities. It is not clear whether the genetic or chromosomal aberrations are causative factors in the initiation of malignancy or simply epiphenomena (vide ante).

The Recognition and Characterization of the Abnormal Stem Cell

In this section, the questions to focus on include: 1) the phenotypic differences between the abnormal cell and its normal counterpart, 2) the nature of the proliferative advantage of the abnormal cell and how it is maintained, and 3) whether the regulatory mechanisms of hematopoiesis are normal or disturbed in the disease state. This situation, which is very complex, is made more so in certain model systems by secondary mutations and selection within the transformed population, leading to a replacement of the

Digitized by Google

[HG004S][GDrive]

original transformed cell with transformed cells more likely to be autonomous. Transformation could conceivably occur at any location in the hematopoietic system. Evidence has accumulated, however, that such disorders as CML and polycythemia vera involve a change at the level of the totipotent stem cell (vide ante).

These diseases are characterized by specific imbalances in the pattern of differentiation. Clearly, a better understanding of factor-cell interactions (vide ante; vide infra) and how they determine differentiation will help explain current observations about these diseases. The acute leukemias are a prototype of the abnormal proliferation of hematopoietic cells. In AML, the blast cells generally do not have a shortened generation time and the increase in blasts is in some way related to a block in the maturation process. We need to continue with a major effort to try to gain an understanding of whether these cells are autonomous (intrinsically programmed to proliferation), under abnormal regulatory influences, and/or are blocked in maturation. Cultures of seemingly normal lymphocytes can be stimulated to grow indefinitely if injected with Epstein-Barr virus or if stimulated by T cell growth factors. Understanding the mechanism of this effect is extremely important. This goal will be aided by the development of systems in vitro for microinjection of proteins, nucleic acids, or antigens.

Leukemic cell lines of a committed cell lineage undergo functional differentiation when exposed to polar compounds, but many do not appear to be under the control of normal regulation. Murine myeloid leukemic blast cell lines exhibit great heterogeneity with respect to differentiation. A major objection to studies on leukemic lines is that these lines are extremely rare and probably do not reflect the true characteristics of cells transformed in vivo. These are, however, undoubtedly useful in understanding gene regulation.

Research Needs

* The development of new genetic systems involving stem cell abnormality.

* Studies of early events in transformation in animal models in vitro to determine whether many cells are initially altered and if the one that predominates has a selective growth advantage or whether the initiating event is clonal.

* Is the unusual chromosomal rearrangement the event that confers the growth potential on the cells, as has been vigorously suggested for Burkitt's lymphoma?

The number of factors regulating normal growth and differentiation within hematopoietic compartments is probably greater than is now appreciated. Little is known about the mechanisms of action of any factor regulating hematopoiesis. An effort should be made to purify all of the important factors; those important in stem cell self renewal, stem cell commitment, cell differentiation, mature cell proliferation, and growth factors utilized by malignant cells. The ultimate goal in each case would be to have a pure factor(s), pure cell type, and an assay system for each category. Assuming that pure growth factor (GF) was available. The

Alabama man key in scientific detective story

By Steve Sternberg
Science/Medicine Writer

Swirling in the blood of Charles Robinson, 28, disc jockey, father of two, was a secret that had puzzled scientists for decades. Its discovery, like many breakthroughs, came unexpectedly.

For Robinson, who died a painful death nearly a decade ago, the discovery of the first human cancer virus meant scientific immortality.

The story began in 1975, when an Alabama doctor found that Robinson, who lived near Mobile, had a rare malignancy known as mycosis fungoides, which starts in the skin and progresses to the lymph nodes and organs.

But Robinson also had weakened immune defenses, and cancer had entered his bones. To learn more, the doctor sent him to the National Cancer Institute labs at Veterans Hospital in Washington, D.C.

"It was clear when Charles Robinson showed up there was something weird," recalls Dr. Paul A. Bunn, who was working at the hospital under a contract to the cancer institute. He took tissue samples for further study.

The research didn't help Robinson, but he managed to make the best of his circumstances.

"He was very jovial despite having a horrible disease," says Bunn. "Initially, he was very sick, then came a remission, then the disease came back."

"He was very fearful," says Dr. Bernard Poiesz, who was then a postdoctoral student at the institute. "His tumor moved very rapidly. It became apparent to him that he did have a lethal disease.

"He never fully realized the impact he made to discovery of HTLV-1. By the time it was fully published, he had died."

The breakthrough was based on a foundation of earlier research.

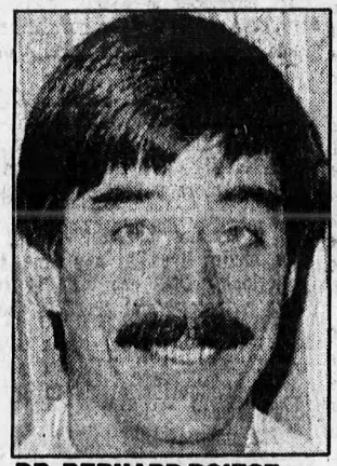
Dr. Robert Gallo of the National Cancer Institute had always been intrigued by the idea of cancer viruses. At first, the interest was intensely personal. At the age of 13, he had watched his younger sister grapple with leukemia.

"It influenced his focus," says one of Gallo's colleagues, Dr. Flossie Wong-Staal, chief of molecular biology at the cancer institute. "Later, the work itself provided the incentive."

Viruses long suspected

Despite the lack of direct evidence, the idea that viruses could cause human cancer had long been rooted in 20th century science.

In 1910, Payton Rous of the Rockefeller Institute found that a virus could cause tumors of muscles, bone and blood vessels in chickens. In 1960, William Jarret of the University of Glasgow discovered a feline leukemia virus.



DR. BERNARD POIESZ: Found chemical evidence that a virus was present.

By the time Charles Robinson became ill, scientists already knew there were animal viruses, called retroviruses, which incorporated themselves into the genetic material of their victims. They knew that unlike other viruses, they could survive indefinitely.

Gallo was convinced there must be such a virus in humans.

"Gallo believed it all along," Bunn says. "There was no question in his mind."

To investigate his theory, Gallo recruited a team of senior scientists and energetic young research fellows. One of them, Dr. Frank Ruscetti, made a crucial discovery — a substance called interleukin-2 that makes white blood cells grow. Without interleukin-2, cells which help defend the body against disease resist growth. With it, they multiply wildly.

But Robinson's "helper T-cells" were unusual. They grew under laboratory conditions without interleukin-2. In 1978, Bunn sent the culture to Poiesz's lab at a cancer institute-sponsored facility in Rockville, Md.

While Poiesz, then 28, was inspecting Robinson's cells for interleukin-2, he also looked for chemical evidence of viruses. In December 1978, he found one. He worked on it for about two months before feeling confident that this was, in fact, from Robinson and not a contaminant.

He called Bunn's lab with the news. "I called them on a Friday," Poiesz says. "I think I said, 'I can't believe it. I think I found a virus in Charley Robinson's cells.' "

"Dr. Poiesz was incredibly excited," Bunn recalls. "When he called to tell me, Dr. Gallo was actually out of town. He showed the data to Dr. [John] Minna, Dr. [Adi] Gazdar and myself. We were extremely excited too — no one had ever seen a human cancer-causing virus."

DR. PAUL A. BUNN: Took samples of Charles Robinson's tissue for further study.

The discussion was held on a Friday in January, in a tiny office in the VA hospital. The researchers listened to the data. They worried that other cells might have contaminated the mixture. "But they all agreed it was a significant finding," Poiesz says.

'Prize-winning discovery'

"It was a prize-winning discovery," says Bunn. "I don't think there was any question in anyone's mind. Possibly the Nobel Prize."

Minna told Gallo about the discovery early Monday morning, in a locker room while both were changing to play tennis.

"He thought it was potentially prize-winning too," Bunn says.

In May 1980, Gallo publicly reported the results for the first time during a meeting at the Cold Spring Harbor Laboratory, in Long Island.

The work was quietly received — until 1981, when doctors began reporting cases of another related disease, AIDS, also caused by a retrovirus.

One year later, Gallo and other researchers were awarded the 1982 Albert Lasker basic medical research award for their work. Although the Lasker award is often a prelude to the Nobel Prize, there are no guarantees. The Nobel also eludes many Lasker laureates.

With the discovery, Gallo increased the research team from a handful of scientists to more than 50. At times, several projects were under way at once.

"We were making a lot of virus, purifying it and characterizing it," Poiesz says. "To make sure the whole operation didn't stop, I stayed up five days in a row. I was so excited and I didn't feel tired."

The next series of experiments nearly soured his optimism. Poiesz had tested patients with mycosis fungoides for the new virus, which Gallo had named human T-cell leukemia virus (HTLV-1). He found none. They had a different disease.

The researchers were puzzled until two things happened.

First, Gallo learned that Dr. Daniel Kitovsky, a cancer specialist at Hammersmith Hospital in England, already had uncovered eight or nine cases of cancer similar to Robinson's.

He used a new test for HTLV-1 developed by Gallo's team at the National Cancer Institute. 'It was dramatic," Gallo says. "All his cases were positive for the virus."

Cluster of cases in Japan

None of the patients had had mycosis fungoides. They had an as yet unnamed disease, which would soon be known as adult T-cell leukemia/lymphoma.

Then the researchers learned of work under way in Japan, where Kiyoshi Takatsuki of Kyoto University reported a cluster of bizarre cancer cases, resembling Robinson's, among people on the islands of Kyushu and Shikoku.

The disease, which Takatsuki called adult T-cell leukemia, infected the blood and bone marrow of its victims. It usually killed them within three or four months.

Until Gallo reported on his work, the Japanese knew of no organism that caused cancer.

While the American researchers were studying Robinson's cells, they encountered a similar case involving a New York City woman who abused drugs and came from the West Indies.

A third case turned up in 1979 — in a tattooed sailor from the merchant marine, who had visited both Japan and the Caribbean. He had both the new cancer and a recently recognized nerve disease — now also linked to HTLV-1.

To study the disease in detail, the researchers needed more cases.

"We wanted to get more cells to study," Bunn says. "The Japanese had all these patients. Gallo's lab and others were instantaneously in competition with the Japanese. But the Japanese didn't want to share their stuff."

In an effort to find their own patients, Gallo's group turned to the Caribbean. In 1980, National Cancer Institute epidemiologist Dr. William Blattner went to Jamaica and consulted with physicians about setting up the research program which is now known as West Indies Project.

In less than a decade, the cells taken from Charles Robinson during an uncomfortable biopsy grew from a cell culture, called HUT 102, into one of the most active and productive medical research efforts of the century.

It has since helped researchers identify new strains of a deadly viral disease that Gallo calls the "first great pandemic of the second half of the 20th century." The disease is AIDS.

The scientists never had a chance to tell Charles Robinson.

He didn't live long enough.

The Great AIDS Quest

Editor's note

The performance of the press in reporting the spread of the AIDS plague, one of the most important stories of the century, was abysmal.

No story caught us more ill-equipped or unprepared. The speed with which the disease spread, its enormously complex nature and the scientific ignorance of the press made it a story simply beyond our capabilities.

When the story moved to the search for and ultimate discovery of the cause of the disease, the combination of complexity and ignorance forced reporters into the role of stenographers, mostly unchallenging and unable to scrutinize. As some critics suggest, the story of the discovery of the AIDS virus has not really been reported at all—until today.

This special section of The Chicago Tribune contains that story, an almost book-length account culminating two years of intense work by one of journalism's premier investigative reporters. John Crewdson, 43, won the 1981 Pulitzer Prize for national reporting while a New York Times correspondent and later became metropolitan editor of The Tribune. Now a special national correspondent for The Tribune based in San Francisco, he has been assigned to the AIDS story almost exclusively since it crawled onto the front pages of the newspapers in mid-decade, not because of any special science or medical background but because Crewdson had proven over the years to be precise, cautious, curious and persistent in pursuit of the most difficult and elusive stories.

Twenty months ago, Crewdson was assigned to document how different segments of society, particularly the scientific community, the public health sector and the political establishment, reacted to the AIDS scare.

The resulting account of the quest for the cause of this mysterious and terrible disease is a classic story in many ways.

It is a story of commitment and dedication to mankind and of tireless, often brilliant detective work within the magic and marvelous world of modern medical technology. But it is also a story of cut-throat competition and bare-knuckled politics, of individual ego and national pride, and of the kind of intense pressure on human beings that often brings out the worst in even the best and can result in lying, cheating and outright fraud.

The presentation of this story, an entire special section consisting of more than 50,000 words spread over 16 pages, is extraordinary, to say the least. But the story itself is so extraordinary as to demand it.

As extensive as it is, this account is still far less complete than The Tribune would like, in part because precise scientific explanation can be so exhaustive and, more important, because early in Crewdson's investigation, Dr. Robert Gallo, a key figure, ceased to cooperate. Not only did he decline repeatedly to answer questions, he fought the Freedom of Information requests for public records and made numerous attempts to discredit Crewdson's reporting and impugn his personal integrity, both with his editors and with members of the scientific community.

Still, the story is by far the most complete and detailed look at how the government and scientific communities reacted to this huge and growing public health challenge. And it casts, perhaps for the first time, a brilliant and penetrating light on modern medical science.

James D. Squires

Science under the microscope

1 'We forgot to write the summary'

By John Crewdson

On the afternoon of the day before his 50th birthday, the American scientist Robert C. Gallo sat down at a small desk in a hotel room in Germany. In the chair next to his was Luc Montagnier, one of the French researchers from whom Gallo had been trying for nearly three years to steal the credit for discovering the cause of AIDS.

Neither Montagnier nor Gallo, the unchallenged AIDS superstar at the National Institutes of Health, was there by choice. The two scientists had been forced together by pressure from their governments, and their peers, to write a combined history of their research that would end their increasingly acrimonious dispute.

The Pasteur Institute, where Montagnier works, had formally challenged the patent on the blood test for AIDS developed in Gallo's lab, and the American government was eager to settle the case. Any settlement would turn on the question of who had been first to find the virus that causes the disease and use it to make a test.

The 'definitive scientific history' that emerged from that hotel room in Frankfurt made possible an agreement between the French and American governments, the first ever to resolve an international conflict over a scientific discovery. Officially, the dispute has been settled forever. In reality, the scientific world has been left with more questions than answers about who really discovered the cause of AIDS, and when and where and how.

In an effort to distinguish scientific truth from gossip, rumor and professional jealousy, The Chicago Tribune undertook a reconstruction of the discovery of the AIDS virus that has included the examination of more than 5,000 pages of government documents and interviews with 150 scientists in this country and abroad.

The story that emerges is less heroic than generally portrayed, but no less dramatic: misstated data and secret experiments, phantom viruses and disappearing genes, unreproducible results and muddled lab notes, mislabeled cultures and misleading photographs.

What also emerges is that the history—inelegant, vastly incomplete and technically inaccurate—even begins with a lie. Between the Gallo and Montagnier laboratories, it says, there had always been 'a spirit of scientific cooperation and a free exchange of ideas.'

As with many histories, the biggest lie is in what it doesn't say. Utterly missing from the account of this great scientific achievement is the story of an influential and intimidating scientist who chased the wrong virus for more than a year, only to reverse course and emerge with a virtual genetic twin of the virus that had really been discovered by his rivals in Paris and delivered to him months before.

What happened in Robert Gallo's lab during the winter of 1983-84 is a mystery that may never be entirely solved. But the evidence is compelling that it was either an accident or a theft.

The beginning of the 1980s looked like the beginning of the end for infectious diseases in America. Smallpox had been eradicated, polio was nearly nonexistent and the childhood illnesses were on the ropes. Then, in the spring of 1981, doctors noticed that a few young men in large American cities were dying horrible deaths. Something was ravaging their immune systems, but what?

As the death toll mounted, so did the theories. Because all the early patients were homosexuals, some scientists thought the disease that would later be called AIDS must be a byproduct of the gay lifestyle. But when the same symptoms began turning up in hemophiliacs and in heterosexuals who had received blood transfusions during surgery, the possibilities narrowed. Any number of infectious micro-organisms might be transmitted in semen or blood, but the only thing small enough to evade the filters used to screen the clotting factor given hemophiliacs was a virus.

In May of 1983, less than two years after the first AIDS cases had been recognized by physicians at UCLA, an anxious nation was relieved to learn that scientists at Harvard and the National Institutes of Health had found an important clue. As many researchers had been predicting, it seemed that AIDS was indeed caused by a virus. What came as a surprise was that the virus under suspicion had apparently been around for years.

Its scientific name was human T-cell leukemia virus, HTLV for short, and it belonged to a relatively small group of viruses known as retroviruses. So far HTLV had been linked only to a rare leukemia found mostly in the fishing villages of southern Japan. Now the experts were suggesting it might also be responsible for what would soon become the biggest public health emergency since half a million Americans perished in the great influenza epidemic of 1918.

One of those making the announcement was Robert Charles Gallo, a veteran researcher and laboratory chief at the National Cancer Institute, the biggest and richest of the research institutes that make up the multibillion-dollar federal biomedical complex known as the National Institutes of Health in Bethesda, Md. Not coincidentally, it was in Gallo's laboratory at NIH that the leukemia virus had first been isolated a few years before, a discovery that had propelled Gallo to the top rank of American medicine. Just six months before the announcement, when Gallo was awarded the Lasker prize, the top honor in American biomedicine and frequently a precursor of the Nobel prize, the citation had lauded his "revolutionary discovery of the first retrovirus known to be associated with a human malignancy."

In the summer and fall of 1982, just as the AIDS epidemic was beginning to grip the public's attention, the most important thing on Gallo's mind was finding out how many people around the world had been infected with his new leukemia virus and the even newer substrain, called HTLV-2, that one of his assistants had just isolated from a Seattle seafood salesman.

Arthur Levine, then chief of the cancer institute's pediatrics branch, remembers a conversation with Gallo about AIDS in June of 1982. From colleagues on the West Coast Levine had become aware of the AIDS epidemic early on, and he also knew a thing or two about retroviruses.

"It was a phone call from me to Bob Gallo," recalled Levine, now scientific director of the National Institute of Child Health and Human Development. "I said, 'Bob, have you heard of this bizarre syndrome that's happening in San Francisco and New York?' He hadn't heard of it. I described it to him, and he agreed that it was very intri-

See AIDS, pg. 3

How Tribune AIDS project was reported

Tribune correspondent John Crewdson began this examination of the scientific research on AIDS 20 months ago. Even though he interviewed more than 150 people in this country and abroad, and reviewed thousands of pages of documents, he wasn't able to answer all the questions surrounding the work of Robert Gallo, a key figure in the discovery of the cause of the disease.

The Tribune sought on many occasions to interview Gallo and some of his associates. Gallo answered some questions in a telephone call in September, 1988, but no in-person interview, at which documents could be reviewed and more extensive questions addressed, was ever granted.

In December, 1988, former U.S. Sen. Birch Bayh, Gallo's Washington-based attorney, sent The Tribune a letter stating that "Dr. Gallo is amenable to your interview request and suggests that it should be arranged expeditiously. We assume that your work will not be published until after the interview has taken place." Bayh also asked for a list of questions.

On Dec. 19, a day before the interview was to have taken place, The Tribune delivered 188 questions, to Bayh's office. Three days later, Bayh's office advised The Tribune that Gallo no longer wished to be interviewed.

In January, 1989, in a telephone conversation with Tribune Editor James D. Squires, Gallo said "the lawyers" had advised him not to grant the interview. In the months that followed there were more letters and telephone calls in which Gallo and Bayh complained about questions Crewdson was asking.

Through Squires, The Tribune again tried to obtain an interview with Gallo, agreeing to send Executive Editor Jack Fuller along with, or instead of, Crewdson. On July 28, Squires sent a letter to Bayh with a revised set of questions. There was no response. In October, The Tribune sent another letter noting that the lack of response was being taken to mean no interview would be granted.

Myron T. Essex, a retrovirologist from the Harvard School of Public Health and a longtime Gallo collaborator, declined a request for an interview because of "a heavy travel commitment and a tight schedule."

Another Gallo collaborator, Harvard biologist William Haseltine, also declined a request for an interview.

Gallo's chief molecular biologist, Flossie Wong-Staal, said in a letter to The Tribune that she did not "have the time or inclination to respond to every naive reporter to satisfy his idle curiosities."

Mikulas Popovic, Gallo's former chief virologist, also declined an interview, saying, "This is not the time to write a history. You should wait for 10 or 15 years."

Even outside of science, Robert Gallo is a celebrity

In just five years, Robert Charles Gallo has become one of the most prominent medical scientists in the world. He has won nearly every award his field has to offer—his biography lists nine single-spaced pages worth—and the hundreds of thousands of dollars in prize money that goes with them. He is the only scientist ever to win two Lasker awards, this country's highest biomedical honor. The New York Times calls him a "strong candidate" for a Nobel prize.

Gallo, who heads the National Cancer Institute's Laboratory of Tumor Cell Biology, is also a celebrity outside the realm of science. When the Italian-American Foundation throws its annual awards dinner, he is there with composer Gian Carlo Menotti. When People magazine chooses its "30 Hardest Working Celebs," he makes the list with Dan Rather and British Prime Minister Margaret Thatcher. Last month, Newsweek magazine counted him among America's 25 "leading innovators." Last week he met Pope John Paul II in Rome.

It is a rare news article about AIDS that does not contain Gallo's generously quoted opinion, and an even rarer conference on the disease where he is not a much-sought-after speaker. So much in demand is he by journalists that those attending last year's international AIDS conference in Stockholm were required to enter a lottery for a chance at a five-minute interview.

Gallo has made scientific careers, and those whose careers have become intertwined with his afford him the highest praise. William Blattner, a National Cancer Institute epidemiologist who has spent much of the last decade searching in different populations for the human leukemia virus first isolated in Gallo's lab, says, "Bob is one of the really great scientists of our time."

Dani Bolognesi, the Duke University virologist who followed Gallo into the field of human retroviruses, is often described as Gallo's closest friend. Bolognesi credits Gallo with "a tremendous amount of intelligence, a great deal of intuition. Bob sees through things and over things and around things in ways that are sometimes difficult for us."

Gallo is respected by other researchers less for his scientific acumen than his ability to see the larger picture. "He is able to synthesize," says Wolf Prensky, chief of virology at St. Clare's Hospital in Manhattan. "It's something that few scientists can do well."

"He is imaginative," says Robin Weiss, the noted British retrovirologist. "He doesn't know the literature well, because he's too busy flying around. He's not scholastic in the pedantic, obsessive way that we ought to be. But Gallo comes out with different ways of looking at things."

"I don't have a great analytical talent," Gallo told The Tribune. "I do think, however, I have some talent in thinking originally. And I have some perseverance and I work hard. But I am not dotting all i's and crossing all t's all the time. It has not been my strength. There are far better scientists than me in that line."

Gallo's strong emphasis on personal loyalty, and his legendary temper, are the reasons given most often by those who know him for declining to talk about Gallo on the record. One former associate spoke for many when he said, "If he died, I might talk to you."

Gallo is not unaware that he inspires controversy. "I have friends and enemies everywhere," he says. "I'm not rewarded by scientific peers. There's a lot of people with a lot to gain by certain things, and there's a lot of jealousy. It provides them with an explanation for their own inadequacies. You know what my flaws are; they're obvious. I tend to be aggressive. I tend to be competitive. I hope to God I don't hurt anybody."

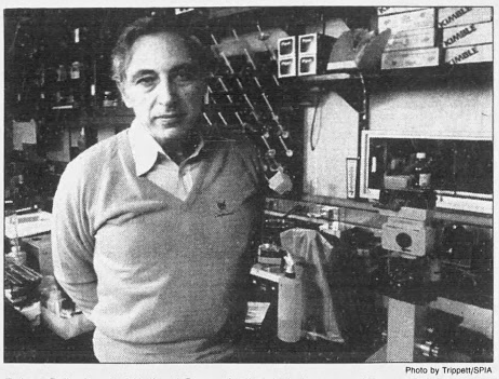

Photo by Trippett/SPIA

Robert Gallo, head of National Cancer Institute's Laboratory of Tumor Cell Biology.

It was Gallo's peers who, until last year, kept him from membership in the National Academy of Sciences, the 2,000-member body that comprises this country's scientific establishment. "He really wanted to be in the academy," says one Nobel laureate. "He would tell you himself that was one of the things that made him unhappy in life."

According to that scientist and others, although Gallo had been proposed for membership several times, on each occasion the selection committee declined to add his name to the ballot. What transpires during academy elections is a closely held secret, but several members confirmed that Gallo finally gained entrance through a process called voluntary nomination in which the selection committee can be bypassed if signatures are obtained from 20 members.

Academy memberships are a plum, but it is the gleaming gold disc with the bas-relief of Alfred Nobel that to a large degree drives science forward. "I don't know if I'll ever get it," Gallo told The Tribune. But he notes that three out of four Lasker recipients have gone on to win the Nobel, including this year's winners, J. Michael Bishop and Harold Varmus of the University of California, both of whom also shared the Lasker prize with Gallo in 1981.

Gallo suggests his two Laskers "ought to mean something" to his chances, and he adds that "the president of the University of Chicago, Leon Jacobsen, has more than once nominated me for a Nobel prize."

Jacobsen, an emeritus professor of medicine at Chicago, where Gallo served his internship and residency in the 1960s, has never been the university's president, and he will not discuss having placed Gallo's name in nomination. "People just don't talk to each other about those things," he says. But Jacobsen does volunteer that he helped engineer Gallo's admission to the National Academy of Sciences.

"We had a hell of a time getting him in," Jacobsen says, "because people are jealous of him. He's published 600 or 700 papers, and he runs a big show. I talked to a lot of these people who are against him, not because of his work but just on principal, whether he was doing too much or publishing too many papers. You know, these things get on some people's nerves, I guess, because maybe they'll put out one a year and he puts out 50."

Gallo's curriculum vitae, nearly a half-inch thick, contains more than 700 scientific articles—a prodigious number even for a scientific superstar. In the last three years alone, Gallo has been a coauthor on more than twice as many articles as any of the other leading scientists in his field. He has not done any scientific "bench work" in years, but in listing himself as an author on most of the papers published by other researchers in his lab, Gallo is hardly alone among the heads of major laboratories.

Several of the articles that bear his name also describe experiments done in other laboratories in which he and his staff played no direct part except perhaps to provide a snippet of DNA or some other piece of raw material. But engineering such collaborations is one of the things Gallo does best. "To be a success in science these days you need a different sort of talent than just the ability to be a good experimenter or ask the right questions," says another cancer institute scientist. "It's become an entrepreneurial business, and Gallo's good at that. He was one of the first of the big-time laboratory operators."

Gallo's laboratory, atop Building 37, a modern concrete-and-glass tower on the edge of the university-style campus of the National Institutes of Health in Bethesda, is the unabashed envy of his colleagues. So is his $8 million annual budget, an enormous sum even for a scientific laboratory that employs more than 50 researchers and support personnel. So is his devoted permanent staff, some of whom have been with him for a decade or more. "It's a very personal operation," says a cancer institute colleague. "That's what everybody wants, to be surrounded by people who will bust their backs to make you look good."

The quality of Gallo's staff is bound to be diminished by the departures of two of his top researchers. Mikulas Popovic, his chief virologist, who played a central role in the isolation of the AIDS virus, left in August for a job at New Mexico State University. Gallo's chief molecular biologist, Flossie Wong-Staal, is said to be leaving Bethesda in January for San Diego.

Each year for the past several years, Gallo has hinted to his friends that he, too, is on the verge of leaving the cancer institute for academia or private industry. At different times he has been rumored to be in negotiations with Duke, Johns Hopkins and Yale and, most recently, with the British financier Robert Maxwell.

The possibility that Gallo might move to Yale was seen by friends as particularly significant in light of his frequently quoted remark a few years back that, because he had attended a lesser-known medical college, he felt the need to work all the harder to prove himself.

Gallo, 52, the only son of a comfortably well-off family, grew up in Waterbury, Conn., where his late father, a metallurgist, owned a small but successful company. Gallo has often said it was the death of his younger sister, Judith, from childhood leukemia that inspired his interest in medical research. After graduating summa cum laude with a degree in biology from Providence College in Rhode Island, he won a medical degree from Philadelphia's Thomas Jefferson University.

In 1965, following his internship and residency at the University of Chicago, Gallo joined the National Cancer Institute as a clinical associate. But after a year of treating cancer patients, an experience he has described as unsettling, he joined the institute's research arm and began a rapid advancement through the ranks, gaining his current position as laboratory chief in 1972.

The rumors of Gallo's departure come and go but Gallo remains at NIH, and those who know him well believe he will never leave. "He never can get a set-up like he's got there now," one friend says, and the cancer institute is happy to see him stay. "In biological research I don't think a supreme personality reigns," says another scientist. "There's no Einstein. He's the only star the NIH has left. He's their big hope for a Nobel prize."

Money and prizes aside, nowhere else will Gallo be able to match the influence he enjoys among those at NIH whose policies determine the course of biomedical research in this country and, to a large extent, the rest of the world. For years, Gallo's position at the cancer institute as first among equals derived from his close personal relationship with the institute's longtime director, Vincent T. DeVita Jr., who resigned unexpectedly last fall to take the No. 2 job at Manhattan's Memorial-Sloan Kettering Cancer Center.

"DeVita and Gallo were very close," says one doctor who knows both men well, and after DeVita's resignation there were fresh rumors that Gallo would not be far behind. But the rumors ceased when DeVita was replaced by Samuel Broder, who worked closely with Gallo during the early years of AIDS research. A former NCI official predicts that "with Broder there, Gallo will still get everything he needs," and Broder's praise of Gallo is unrestrained.

"Gallo is one of the paradigmatic figures of the 20th Century," Broder told the Washington Post. "He's influenced things in our daily lives to an incalculable degree. Einstein, Freud—I'd put him on a list like that, I really would."

In right place at right time, three French scientists make history

When Luc Montagnier arrives for work at the Pasteur Institute, it's not uncommon for him to find someone with AIDS waiting outside his lab. The reason is always the same: the hope that somehow the scientist who discovered the virus that causes the disease will know how to cure it. "These poor AIDS patients," Montagnier says with a shake of his head, "they regard me as a god, you see."

Although Montagnier's work with AIDS has brought him an international reputation, he is regarded as less than a god by his colleagues at the Pasteur. Earlier, his most noteworthy achievement came in the mid-1960s; as a young scientist in London, he developed a method for growing animal cancer viruses that is still widely used.

Last year, when Montagnier offered himself as a candidate for the Pasteur's directorship, a position filled by a vote of the faculty, he reportedly lost by a large margin. Now he is "in discussions" with financial backers in California who want him to head a new research institute in La Jolla that will be devoted to the search for an effective treatment for AIDS.

"My motivation comes back to the patient," Montagnier says. Although he would like to oversee the La Jolla institute while keeping his position in Paris, he acknowledges that might not be possible. "As I view it now I won't be leaving Pasteur," he says. "But if I'm forced to leave I will leave, of course."

Montagnier, 57, grew up in a small town south of the Loire Valley during the World War II. "My father was an accountant," he says. "It was the dream of my parents that I should become a doctor. It was the first time in my family somebody went to college. But I decided I should study not only medicine but also science. I was more interested in science."

Jean-Claude Chermann also began his education with the idea of becoming a doctor. "I came from a very poor family," he says. "My parents were divorced since I was 4 years old. My mother was a seamstress, and at night she was an usher in the theater. I did not want to be a scientist. I would like to be a physician, a surgeon. But I have to work for paying my study and so on, and I decided that it was too long to make physician."

Chermann had been at the Pasteur only a few years when, in the early 1970s, he was approached by a friend of a friend, a young student named Francoise Barre. The only child of a middle-class Parisian family, Barre had played with microscopes and chemistry sets. "I was always interested in the mechanisms involved in human life," she recalls.

As a University of Paris undergraduate, Barre eventually faced the same decision as Montagnier and Chermann, whether to become a doctor or to go into pure science. Hoping hands-on experience would help her decide, she asked Chermann for a job in his lab. After she graduated the job became full time. In 1975, when Chermann elected to work on retroviruses rather than antiviral drugs, Barre remained at his side.

Chermann's decision would irrevocably alter the course of both their careers and their lives. In late 1982, Montagnier, by then the Pasteur's chief of viral oncology, was asked by a group of Paris physicians to look for a retrovirus in patients suffering from a new disease of the immune system. Chermann and Barre were the only other scientists in his unit experienced in isolating and growing retroviruses. Within a few weeks, Montagnier, Chermann and Barre had discovered the virus that causes AIDS.

Glossary

AMINO ACIDS: the building blocks of **proteins**. Although there are hundreds of amino acids, only 20 are ordinarily found in proteins.

ANTIBODIES: Protein chains produced by the immune system that bind to, and often neutralize, **viruses** and other invaders. Viral antibodies are a sign that the virus is, or has been, present.

ATLV: Adult T-cell leukemia virus, the name given by Japanese scientists to the virus that they discovered, which is the same as Robert Gallo's **HTLV-1**.

B-CELL: The immune system cell involved in producing **antibodies**. A line of cancerous B-cells, called BJAB, was used by the French to grow the AIDS virus called **LAV**.

DNA: Deoxyribonucleic acid; long chains of chemical compounds called **nucleotides** that contain genetic code for assembling proteins. The DNA containing the genetic code for the AIDS virus has about 9,200 nucleotides. By contrast, the DNA code for a human being has about 3 billion nucleotides.

ENZYME: Biochemically active **protein** that regulates viral and other biochemical activities. The enzyme the AIDS virus uses to reproduce itself is called **reverse transcriptase**.

H9: a permanent line of **T-cells** created in Gallo's lab by cloning a single T-cell from an established T-cell line called **HUT78**. When the H9 cells began to multiply, they were infected with the pooled AIDS virus that became known as **HTLV-3B**.

HIV: Human immunodeficiency virus, the generic name for the virus that most scientists believe causes AIDS.

HTLVA: The name given to what may have been an AIDS virus isolate used in experiments in Robert Gallo's lab in early 1984. The derivation of the term is unclear because the existence of such a virus was never publicly acknowledged.

HTLV-1: Human T-cell leukemia virus isolated in Gallo's lab. The first retrovirus associated with cancer in humans, it infects **helper T-cells** and causes them to proliferate wildly. Japanese scientists established a connection between HTLV-1 and adult T-cell leukemia.

HTLV-2: Variant of **HTLV-1**, also isolated in Gallo's lab. HTLV-2 was found in 1981 in a patient code-named MO. It has since been discovered in fewer than a half-dozen patients with an extremely rare disease called hairy cell T-cell leukemia, but scientists are unsure whether the virus is the cause of the disease.

HTLV-3: Gallo's original name for the human retrovirus that causes AIDS. The name was later changed to **HIV** after it became clear the AIDS virus was not related to **HTLV-1** and **HTLV-2**.

HTLV-3B: Gallo's principal AIDS virus isolate, reportedly obtained by pooling tissue culture fluids from 10 individuals in the **H9** T-cell line. Several distinct AIDS virus **DNAs** have been cloned from HTLV-3B that are genetically indistinguishable from the French AIDS virus called **LAV-1**.

HUT78: Human **T-cell** line established in the late 1970s by NCI researcher Adi Gazdar. The progenitor of the Gallo cell line called **H9**, HUT78 was also used in Gallo's lab to grow the French AIDS virus called **LAV-1**.

AIDS

Continued from page 1

guing. And then I said the most intriguing thing is that I think the cause of this syndrome is going to be a retrovirus related to HTLV. He said that's very interesting and got off the phone."

The "bizarre syndrome" was being watched most closely by the federal Centers for Disease Control in Atlanta, where a small group of researchers was hunting frantically for its cause. In the fall of 1982, it occurred to a young CDC virologist named Cy Cabradilla, who had done his postdoctoral fellowship at the cancer institute a few years before, that one of Gallo's two human retroviruses might have something to do with AIDS.

"We were looking at every virus we could get our hands on to see if there was any relatedness," Cabradilla said. "The only one we hadn't really looked at was the human retrovirus. I made an appointment to go up and talk to Bob about evaluating some blood samples for us against HTLV. I spent an afternoon up there. He didn't seem that interested. I don't think he wanted to get involved with a gay disease. I think what turned him around was Max."

"Max" was Myron T. Essex, one of Gallo's longtime collaborators and a senior researcher at the Harvard School of Public Health. Using an established laboratory technique called an immune fluorescence assay, Essex had been testing blood samples from young homosexual men with this newly reported wasting disease.

In the Essex test, the patient samples were exposed to cultures of white blood cells that were known to be infected with the leukemia virus. If the blood contained antibodies to the virus—antibodies are proteins manufactured by the immune system to neutralize invading viruses and other microbes—they would presumably stick to the virus in the cells. When the cells were examined under an ultraviolet light, those to which antibodies had become attached would glow with an iridescent sheen.

Essex was finding that impressive percentages of the samples were positive, an indication that the AIDS patients were infected with the leukemia virus. According to Essex, however, his test was not picking up antibodies to the leukemia virus itself but to a mysterious new protein that seemed to appear on the outer surface of the virus-infected cells as a product of the process of infection.

Essex's data were hardly conclusive, but they were tantalizing nonetheless. As one member of Gallo's staff recalled later, when Gallo first heard about what was going on in Essex's lab at Harvard, "it was like Christmas." For Gallo, the idea that his obscure leukemia virus might be the cause of AIDS made a certain amount of scientific sense.

For one thing, the leukemia virus infected a particular kind of white blood cell known as a helper T-cell, and it was a shortage of helper T-cells that was apparently causing AIDS patients to fall ill with various exotic diseases by robbing their immune systems of the ability to respond to infection. For another, the leukemia virus was a retrovirus, and there was evidence that an animal retrovirus, feline leukemia virus, could cause the same kind of immune deficiency in house cats.

Because so many AIDS patients were homosexual men, many scientists assumed that whatever was causing the disease was transmitted sexually—and so, they thought, was HTLV.

But even if Essex was right, finding antibodies to a protein on the surface of leukemic T-cells was like finding the footprint outside the window after the burglar had fled. Gallo wanted to catch the burglar in the act by finding AIDS patients who were infected with the leukemia virus itself.

From doctors and hospitals around the world, blood and tissue cells from patients with AIDS or pre-AIDS, the collection of lesser symptoms that often precede the disease, had begun arriving in cartons of dry ice at Gallo's laboratory on the top floor of Building 37 on the NIH campus. After the samples were logged in they were tested for reverse transcriptase, the enzyme that retroviruses manufacture in order to reproduce themselves. Those that tested positive were examined for evidence that Gallo's leukemia virus was present in their cells.

The early results were encouraging. Within weeks, Gallo's assistants had detected the leukemia virus in the white blood cells of two East Coast homosexuals, a young Haitian woman named Marcellin who had died of AIDS in Paris, and a 31-year-old Frenchman named Claude Chardon who had been given a blood transfusion in Haiti after losing his left arm in a motorcycle accident.

Including the two East Coast homosexuals and Marcellin, nearly all of those outside Japan in whom the leukemia virus had been found were black. Daniel Catovsky, a researcher at London's Hammersmith Hospital, had discovered it recently in several Caribbean immigrants there, and some scientists were beginning to wonder whether blacks were somehow genetically predisposed to infection with HTLV-1. Most of the infected blacks didn't have AIDS. On the other hand, nearly all of those who were sick with AIDS were both white and homosexual. Chardon seemed to represent some kind of bridge. He wasn't black, and according to his widow he wasn't gay. If Chardon had the leukemia virus and he also had AIDS, then perhaps the two really were connected.

The cells from Marcellin and Chardon had been brought to Gallo in February of 1983 from Paris by a French immunologist named Jacques Leibowitch. When Leibowitch heard about Chardon's case from doctors at the Saint-Lazare Hospital in Paris, he had been quick to recognize its significance. "I was there at the seminar where they presented the case," the Harvard-trained Leibowitch recalled, "and I was strongly motivated to get the cells of this guy. It could serve the purpose of demonstrating that the cause of AIDS was not homosexually related."

In early March of 1983, Gallo sent a paper reporting the detection of his leukemia virus in the two East Coast homosexuals to Science magazine, a weekly published by the American Association for the Advancement of Science and second only to the British journal Nature as a prestigious forum for biomedical research. In a cover letter to the magazine's editors, Gallo made clear he was not claiming the leukemia virus caused AIDS. Rather, he hoped his findings might "direct research in AIDS toward a class of agents not addressed in the literature to this point."

Within a few weeks Gallo had sent Science a second paper, this one reporting that the leukemia virus had now actually been isolated from one of the two East Coast homosexuals and had also been detected in the cells of Marcellin and Claude Chardon. In the meantime Essex had submitted a paper of his own to Science, reporting that up to 40 percent of the AIDS patients whose blood he had tested had antibodies to the mysterious protein on the surface of leukemic helper T-cells. Harvard University, which like most universities owns its faculty members' inventions, promptly applied for a patent on the Essex test.

A few weeks before publication of the papers, Gallo presented his superiors at the National Cancer Institute with a bold proposal. The NCI, he wrote, should move quickly to take the lead in what seemed likely to become a fierce scientific and medical battle against AIDS. A special AIDS working group was needed, Gallo said, and he suggested that he be named its chief of research, an additional responsibility that would require more laboratory space and personnel, but only "until the problem is solved or [for] three years, whichever comes first."

When the papers from Gallo and Essex appeared in the same issue of Science in May of 1983, they made a considerable splash. The Washington Post called the possible involvement of Gallo's leukemia virus "the strongest clue yet to the cause of AIDS." The Boston Globe nominated the virus as "the leading suspect for causing the illness." Even Science's archrival, Nature, took note of "an important group of papers" that "confirms that HTLV is indeed somehow linked with AIDS."

More than 1,200 Americans were already sick with AIDS. Physicians in San Francisco, New York and other big cities were seeing new patients each week, and they were becoming increasingly anxious to know more about the mysterious and deadly disease with which they were confronted. Now they were being told that AIDS might be caused by a leukemia virus. To some, the idea that a cancer virus might underlie an immune deficiency didn't make immediate sense, but most of those who read the articles in Science put their confusion down to lapses in their own understanding of retroviruses and AIDS. The relatively small number of scientists who knew something about retroviruses did have some questions, however.

The curious thing about Essex's data, they thought, was that his numbers were neither high nor low—not high enough to show a conclusive link between the leukemia virus and AIDS and not low enough to be a coincidence. But Gallo and Essex agreed that Essex's test needed to be refined, and they had answers for the other objections as well. When it was pointed out that there was no AIDS in southwestern Japan, where the leukemia virus was most common, Gallo suggested that maybe AIDS hadn't been noticed there yet, or that Japanese people perhaps responded differently to the disease.

The news accounts about the possible link between HTLV and AIDS—and there were many in the spring and summer of 1983—barely mentioned a fourth paper in the same issue of Science. The lapse was perhaps understandable since the magazine itself, in an accompanying news article, had dispensed with the paper in a single sentence. When the nonscientific press referred to the paper at all, it was mostly as an afterthought, to note that researchers at the Pasteur Institute in Paris had provided confirmation of the findings by Gallo and Essex.

The origins of the AIDS work in Paris traced back to the end of 1981, when a group of physicians began meeting informally to discuss what one member, a young immunologist named David Klatzmann, called "a disease which at that time interested nobody." Jacques Leibowitch was also a part of the Paris group, and it was he who focused the group's attention on the possibility that a retrovirus was responsible for AIDS.

"None of us was a retrovirologist and we had no idea what this virus was," Klatzmann recalled. "We discussed how to isolate such a virus, and we reasoned that maybe the lymph node was the best point to look at." Another member, Francoise Brun-Vezinet, had taken a course in virology at the Pasteur Institute and remembered the name of one of her lecturers. In mid-December of 1982 Brun-Vezinet put in a call to Luc Montagnier, the chief of the Pasteur's department of viral oncology. Yes, Montagnier said, he had heard about AIDS and had thought about the possibility that a retrovirus was involved. If the clinicians would bring him a lymph node from someone with AIDS, he would look for such a virus.

The French physicians had already decided the best place to look was the cells of someone who did not yet have full-fledged AIDS. If a virus was present, and if the virus was infecting the helper T-cells, then a person in whom the disease was not so advanced might have more infected cells in which to find the virus. As it happened, another of the Paris clinicians, a tropical disease specialist at the Claude Bernard Hospital named Willy Rozenbaum, had been seeing just such a patient, a young homosexual named Frederic Brugiere.

A fashion designer, Brugiere had been suffering for several months from the persistently swollen lymph glands that often precede AIDS. Other than that, however, he was healthy. On the afternoon of Jan. 4, 1983, Francoise Brun-Vezinet delivered a slice of Brugiere's lymph node to Jean-Claude Chermann, who worked under Montagnier as a lab chief at the Pasteur. Chermann gave the sample to Montagnier, who minced the tissue and put the T-cells he extracted into a flask filled with nutrients to keep them alive. To encourage the growth of any virus that might be present in the cells, Montagnier added an antibody designed to counter the effects of interferon, a protein produced by the immune system that protects T-cells against viral infections.

Because the flask was stored in an incubator that kept it at body temperature, if a virus was present it should begin reproducing in the laboratory just as it would in Brugiere's body. If it happened to be a retrovirus, the first evidence of its existence would be the activation of an enzyme called reverse transcriptase as it assembled DNA copies of the virus's native RNA.

In one sense, the AIDS epidemic could not have come at a better time. If AIDS had appeared even a decade earlier, researchers would not have known where to begin searching for its cause. Helper T-cells had not yet been recognized as a separate class of white blood cells, retroviruses in humans were unknown and there were no reliable tests for reverse transcriptase. Now, however, there was such a test. Every three days Montagnier drained fluid from the culture and gave it to Francoise Barre, another Pasteur scientist who worked for Chermann and who was skilled at using radioactive isotopes to measure the amount of DNA being synthesized by a retrovirus.

Seven times, at three-day intervals, Barre tested the culture fluids for reverse transcriptase, and seven times the results were negative. But on Jan. 26, 1983, when the radioactivity in the fluids reached 5,600 counts per minute—about three times the background radiation at the Pasteur—Barre began paying attention. Three days later, when the radiation level reached 22,000, it seemed only one conclusion was possible: a retrovirus was growing in Frederic Brugiere's cells. Then the numbers on the radiation meter began to fall.

"The first reaction was to think that we had tissue culture problems," Barre recalled, and such a conclusion was understandable. When Gallo's leukemia virus, then the only known human retrovirus, was growing in a culture, the reverse transcriptase level didn't rise and fall; it simply continued to rise as the virus transformed increasing numbers of white blood cells into cancer cells. But the cells in the French AIDS virus culture weren't multiplying as they would have in the body of a cancer patient; they were dying.

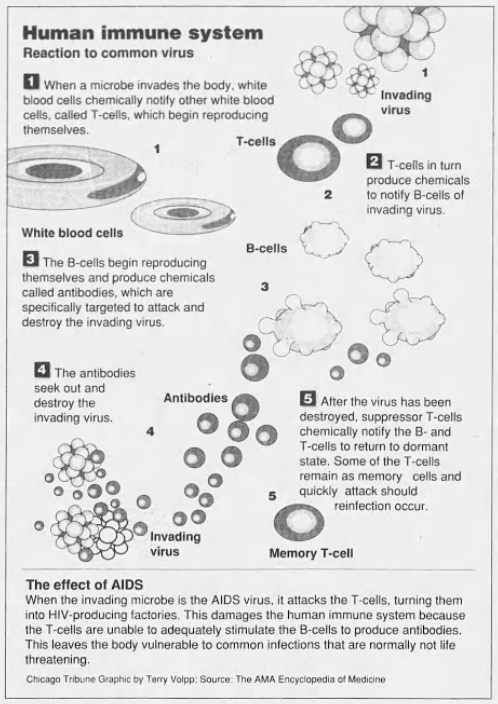
If AIDS was characterized by a decline in the number of helper T-cells, and if a virus was infecting those same cells, then perhaps there was nothing wrong with the culture medium after all. Perhaps it was the virus that was killing the cells. That would explain not only the decline in reverse transcriptase activity and the dying cells, it would also explain the clinical progression of AIDS.

The Pasteur group's solution to the question of how to keep the virus growing was both simple and elegant. "We decided," Barre says, "to add fresh cells." When a second attempt was made to grow the virus, Brugiere's cells were mixed with fresh T-cells from blood recently donated by a Spanish tourist at the Pasteur's hospital. There was nothing special about the Spaniard. "I was in a hurry," Montagnier recalled. "The first donor who came along was the right one."

When the new culture was tested for reverse transcriptase on Feb. 14, the results were negative, and they were still negative on the 17th, the 20th and the 22d. But on Feb. 27, the radiation level began to climb, and on March 1 it peaked at 14,000. Three days later it began to fall, but this time there was no concern about possible tissue culture problems. Indeed, the excitement in the Pasteur's small AIDS group was palpable. But just to be sure, the group wanted to reproduce the same result one more time. From Montagnier's crowded lab, the culture was moved to its own room, across the hall from Barre's office on the first floor of one of the Pasteur's oldest buildings.

Because the Spaniard had gone back to Spain, when Barre and Chermann in-

Continued on following page



Antibodies: Weapons that target specific intruders

The human immune system fights disease with many weapons. Among the most formidable are antibodies, the biochemical medicine the body uses to cure everything from influenza to pneumonia—and, once cured, to protect itself against a recurrence.

Anything that is not a natural constituent of the body—anything "foreign"—may elicit an immune response, including the production of antibodies that are specifically designed to neutralize the invader. When a patient's body "rejects" an organ that has been transplanted from someone else, it is because the patient's immune system has recognized the heart or liver as something foreign.

In cases of infectious disease the foreign invader is often a virus, a particle a few millionths of an inch in diameter constructed primarily of proteins. As soon as the presence of a virus is noted by the immune system's sentinel cells, a biochemical message is passed to other cells that an invasion is underway.

Like a locksmith who fabricates a key from a wax impression of a lock, the immune system's complex machinery assembles a set of antibodies that have a unique biochemical attraction to the proteins of the invading virus.

When an antibody molecule recognizes a passing virus particle in the patient's bloodstream or tissue, it attaches itself to the virus and renders it harmless. If the person is otherwise healthy and his immune system is functioning properly, he will usually recover after all the virus particles have been neutralized. And because the immune system "remembers" the biochemical makeup of each invading virus, any future attack will be met with such a rapid immune response that the patient will probably never again experience any symptoms of disease.

The vaccines that protect against viral diseases like measles and polio are made with altered versions of the viruses that, although altered, still trigger the production of protective antibodies.

Whether there will ever be an effective vaccine for AIDS is still an open question. Although antibodies to the AIDS virus usually appear within several months of the initial infection, they almost always fail to eradicate the virus; there are only a few cases on record of patients who are antibody-positive and virus-negative, suggesting that the AIDS virus may have been eliminated by their immune systems.

Precisely why the immune response to AIDS is so ineffective is not yet fully understood, although it probably has something to do with the fact that during the first several years of infection the AIDS virus lies quiescent inside the very cells that control the patient's immune system—the helper T-cells—and also with the degree to which the AIDS virus alters its genetic makeup as it replicates inside the patient's body.

When the AIDS virus finally does begin to replicate, it destroys the ability of the T-cells to perform their protective function. With his immune system gravely impaired, the AIDS patient eventually dies of some otherwise nonfatal disease against which his body could no longer mount a defense. Because of the absence of T-cells and their inability to generate antibodies in the later stages of AIDS, patients who are seriously ill often test negative for antibodies to the AIDS virus.

LAV: Lymphadenopathy-associated virus, the name originally given by scientists at the Pasteur Institute to the AIDS virus they discovered in 1983. The original French isolate, found in T-cells from Frederic Brugiere, the patient known as BRU, was called **LAV-1**. Like **HTLV-3B**, LAV-1 contains several distinct AIDS virus DNAs, at least two of which are genetically indistinguishable from variants cloned from Gallo's HTLV-3B.

LENTIVIRUS: A class of slow-acting **retroviruses** including the AIDS virus. Before AIDS, lenti-retroviruses had been found only in animals.

LEUKEMIA: Cancer marked by the uncontrolled proliferation of white blood cells which can take several different forms depending on which cells have become cancerous. Cancers of lymphocytes such as T- and B-cells outside the blood are lymphomas.

MOV: The name used in Gallo's lab for an AIDS virus isolate in late 1983 and 1984. The initials apparently stand for "MO Variant," stemming from the belief among Gallo's assistants that the AIDS virus was genetically similar to HTLV-2. What became of MOV is unclear, because its existence was never publicly disclosed.

NUCLEOTIDES: Chemical building blocks of **DNA** and **RNA**. DNA is composed of four nucleotides: adenine, guanine, thymine and cytosine. RNA substitutes uracil for thymine.

PROTEINS: Chains of **amino acids** varying greatly in size and shape. **Enzymes** and hormones are biochemically active proteins. The AIDS virus has several structural and regulatory proteins including its main core protein, called p-24, and its envelope protein, gp120. The numbers refer to approximate molecular weights (in thousands).

RETROVIRUS: Virus whose genetic code is written in **RNA** rather than **DNA**. Retroviruses reproduce by using **reverse transcriptase** to copy RNA into DNA.

REVERSE TRANSCRIPTASE: The enzyme **retroviruses** manufacture to enable them to reproduce inside a host cell.

RNA: Ribonucleic acid; single-stranded chain of **nucleotides** that contains the genetic code for some viruses, including **retroviruses**. Various forms of RNA also assemble **proteins** according to instructions contained in **DNA**.

SERUM: The pale yellow fluid left over after the cells have been removed from blood. It is used for testing for viral antibodies.

T-CELLS: The "controllers" of the human immune system. **Helper T-cells**, also known as T-4 cells, direct the production of **antibodies** by **B-cells**. Suppressor T-cells signal the immune system to "stand down" after a virus or other invader has been vanquished.

TI7.4: Human **T-cell** line established at M.D. Anderson Hospital in Houston. Along with **HUT78**, it was used in Gallo's lab to grow the French AIDS virus called **LAV-1**.

VIRUS: Infectious organism consisting of nucleic acid, either **DNA** or **RNA**, and **proteins**, sometimes contained in protective envelope of fatty material. Some viruses are harmless; others cause disease by damaging the cells they infect.

WHITE BLOOD CELL: Immune system cells that circulate in the blood and of which there are several types, including the lymphocytes called **T-cells** and **B-cells**.

Continued from preceding page

fected the culture for a third time they used T-cells from umbilical cord blood supplied by a nearby maternity hospital. Cord blood cells, as they are called, are among the most susceptible to infection by a virus because the newborn babies from which they come are mostly virus-free. On March 14, when the reverse transcriptase level again reached 14,000, two important conclusions were unavoidable: "First, that the virus was killing the cells," Chermann said. "And secondly, that we have to add fresh cells to keep the virus growing. That was the most important thing."

Besides the presence of reverse transcriptase, there were other indications the Pasteur group had found a retrovirus. Tests showed that the virus's genetic material was RNA rather than DNA, and also that the virus particles were the right size and density for a retrovirus. When some of the infected cells were placed under an electron microscope, which uses beams of electrons rather than rays of light to "see" exceedingly tiny things, the resulting photographs showed what looked like retroviral particles budding from the surface of an infected T-cell.

But which retrovirus was it—Gallo's leukemia virus or a new human retrovirus altogether? The photographs were indistinct, but Chermann and Barre didn't see how it could be the leukemia virus. That virus made T-cells multiply rapidly, and this one was killing them.

In February of 1983 Montagnier called Gallo to say the Pasteur group had found what looked like a new retrovirus in an AIDS patient in Paris. Whether it was Gallo's leukemia virus or not wasn't clear, but if Gallo would send the French some antibodies to the leukemia virus they could find out. The request piqued Gallo's curiosity about what was happening on the other side of the Atlantic. "He was very interested," Barre recalled. "He told us that he also had some data indicating that HTLV could be involved in this disease."

The antibodies Gallo sent to Paris were designed to recognize the two main proteins that form the core of the leukemia virus. If they reacted with the virus growing in the Pasteur's culture, then it must be the leukemia virus. But when the antibodies were added to the culture, there was no reaction at all. "It was for us," says Chermann, "the first proof that the virus was different."

In early April, Montagnier informed Gallo that the antibody tests had been negative and that the French now believed they had found a new human retrovirus related to AIDS. "I said we were close to writing a paper," Montagnier recalled. "He said you have to hurry because we also have written some papers [and] Essex also has done it, and perhaps we could have all the papers in the same issue of Science."

Over a weekend, Montagnier and Barre, whose English was more fluent than Chermann's, hammered out a manuscript reporting the isolation of their new retrovirus from Frederic Brugiere, who would henceforth be known in the scientific literature as BRU. Listed first among the authors, the position traditionally reserved for the researcher who has made the greatest contribution to the work, was Francoise Barre. Chermann's name was second, followed by Brun-Vezinet and Rozenbaum. As the senior scientist in the group, Montagnier was last.

The French paper took careful account of the differences between the virus isolated from BRU and Gallo's leukemia virus. There hadn't been any reaction between their virus and the leukemia virus antibodies. Nor had any of the antibodies in BRU's blood reacted with the leukemia virus, which meant that BRU wasn't infected with HTLV-1. The two viruses, the paper concluded cautiously, were "not immunologically related," and the rest of the article was just as carefully worded. The French would have been rash to claim their virus was the cause of AIDS, and they didn't. Its role in the disease, they said, "remains to be determined." Still, the evidence suggested that they had found something new.

Rather than consign such an important article to the mail, Montagnier handed the finished manuscript to his technician, Jacqueline Gruest, who was on the way to visit her daughter in Washington, D.C. But instead of asking her to deliver it directly to Science, he told her to take it to Gallo in suburban Bethesda.

As with most major scientific journals, papers that are to appear in Science are subjected to peer review, an anonymous evaluation of their strengths and weaknesses by other experts in the same field. While a positive review does not ensure publication, a negative review usually means a paper will be rejected. Unlike any other major journal, however, Science allows its prospective authors to suggest their own reviewers, and when Gallo volunteered to review the paper Montagnier quickly agreed.

Once he had the paper in hand, Gallo noticed that the French had neglected to write an abstract, the long summary paragraph that precedes most scientific papers and other scholarly articles, and the absence of an abstract was more than a minor omission. The abstract is as much as many readers of scientific journals are willing to digest. Moreover, it is the only part of a paper reproduced in the electronic databases that are now the most common tools of bibliographic research. Gallo, however, stood ready to help. "Gallo called me," Montagnier said, "and since the time was very short he said to me that he should write the summary."

On April 19, 1983, Gallo sent the Pasteur paper to the editors of Science with a strong letter of recommendation signed by himself and two of his top assistants. "This paper," the three reviewers agreed, "is of obvious immediate great importance and relevance. It will be of very great interest to virtually all scientists and clinicians. The work is careful. The discussion is clear and well-thought-out. It should be published as rapidly as possible." Gallo also included his abstract with the manuscript, but his summary of the French research made it sound as though the virus in BRU's lymph nodes was either the Gallo leukemia virus or a very close relative.

The abstract began by calling the French virus a C-type retrovirus, the same class of retrovirus to which the leukemia virus belongs. It also said that the protein at the core of the French virus was similar to the core protein of the leukemia virus, and that antibodies in BRU's blood had reacted with some of the leukemia virus's proteins. Gallo had also added a sentence to the text of the paper itself. "The virus," he wrote, "appears to be a member of the human T-cell leukemia virus (HTLV) family."

Montagnier remembers being "confused on the phone" as Gallo read the French his abstract, and Barre recalls that "it was very difficult by phone to object" because "you cannot read, you just hear." Only when they saw the abstract later did the Pasteur group realize it didn't accurately reflect the conclusions in their paper.

The French hadn't determined, for example, whether their virus was a C-type or not. "I was very cautious," Montagnier recalled. "I was not saying it was something different from a C-type." Montagnier was also distressed by Gallo's description of the core proteins of the two viruses as similar. "I would not ever agree to that," he says now, "because we showed no cross-reaction" between the French virus and Gallo's antibodies. "This was misleading. The core proteins did not cross-react."

Nor was there any evidence in the French paper to support Gallo's assertion in the abstract that antibodies in BRU's blood had reacted with the proteins of the leukemia virus itself. The French had seen a reaction between BRU's blood and something on the surface of T-cells infected with the leukemia virus, an effect not unlike the one Max Essex was seeing at Harvard. But they thought the reaction involved a protein that was part of the cell itself, not one that belonged to the virus. "We didn't believe it," Barre said in a recent interview in Paris, pointing to a page in her lab notebook where the data is marked with an arrow. "We didn't think it was reacting with the virus."

There were other surprises. Montagnier said he thought Gallo had added the sentence saying the French virus was a member of the "HTLV family" to the abstract rather than to the text of the paper. It was also his understanding, he said, that Gallo had agreed to change what the "L" in HTLV stood for from "leukemia" to "lymphotropic," meaning a virus that has an attraction for white blood cells.

Whatever the French had found growing in BRU, they knew it wasn't a leukemia virus, and Montagnier wasn't even sure the viruses were closely enough related to bear the same general name. "I believed myself that this was wrong," Montagnier recalls, "but I could not really say this is wrong to Gallo, because I had too little evidence at that time."

Although the antibody reactions and the distinctions between the core proteins were crucial to understanding what the French had discovered, they were lost on those who wrote the government news releases and those who read them. A typical report was the one in the Washington Post, which announced that three independent groups of researchers, at Harvard, the National Cancer Institute and the Pasteur Institute, had "all found signs of human T-cell leukemia viruses" in patients with AIDS and pre-AIDS.

Even those scientists working in the same field were confused by the abstract of the French paper. "Everyone thought the French had isolated HTLV too," recalled Jay Levy, a virologist at the University of California medical center in San Francisco. As it began to dawn on the French that their work was being viewed not as an original and potentially important discovery but merely as support for the findings of Gallo and Essex, the elation in Paris gave way to dismay. "We were not very happy," Francoise Barre recalls with her typical understatement. "That's for sure."

Gallo's response to the expressions of displeasure from Paris was to portray the Pasteur group as ingrates whose paper would never have been published in Science without his intercession. "When Montagnier's paper was submitted to Science, I held back mine so he could join," Gallo said in a telephone conversation with The Tribune last year. "No one's ever written this—I don't think I've ever told a reporter before—that Montagnier's paper was rejected by Science, that I intervened and got it accepted. Doesn't that tell you a little bit about my motives?"

Montagnier is unaware of any such rejection—"all I ever heard," he says, "was that my paper had been accepted"—and correspondence from Gallo's files shows that he forwarded the paper to Science with his glowing review just four days after it reached Bethesda. Asked how the French manuscript could have been rejected by other reviewers during the short time it was in Gallo's hands, Ruth Kulstad, the Science editor who handled the paper, would say only, "Everything here is confidential, and we do not discuss papers, authors or referees."

Nearly five years later, sitting in his cramped office in the virology complex at the Pasteur Institute, Luc Montagnier remembered Gallo's motives less than charitably.

"He was not against me writing a paper," Montagnier said, "but he thought my paper would support his own paper on HTLV. Because he thought my virus was HTLV. Gallo didn't believe there could be more than one kind of human retrovirus. He was fully convinced that HTLV was the right one, that there was only one human retrovirus involved in AIDS."

2 The father of human retrovirology

Retroviruses have fascinated scientists since they were discovered in animals early in this century. Until Gallo's HTLV, however, the only known retroviruses were those that caused cancer and other diseases in animals, and a small group of foamy-looking retroviruses in humans that didn't seem to cause any disease at all.

The idea that retroviruses might have something to do with cancer in humans had been talked about for years, and it was a prospect that had vast implications for medicine. If it were possible to "catch" some kinds of cancer the same way one caught polio or smallpox, it might be possible to wipe out such cancers through vaccination the same way polio and smallpox were being eradicated.

When then-President Richard Nixon signed the National Cancer Act of 1971 and declared his "war on cancer," there was genuine hope that the effort might ultimately produce a cancer vaccine. But the promise of those early years has gone almost entirely unfulfilled. Only one human retrovirus, Gallo's HTLV, has been indisputably linked to cancer, a rare cancer called adult T-cell leukemia.

There was more reason for hope in the spring of 1970, when researchers at the University of Wisconsin and the Massachusetts Institute of Technology announced their nearly simultaneous discoveries of an enzyme called reverse transcriptase, the missing piece to the puzzle of how human retroviruses work.

When David Baltimore, the MIT scientist who would share the Nobel prize for reverse transcriptase with Wisconsin's Howard Temin, was invited to the National Institutes of Health to talk about his great discovery, Gallo was in the audience. "After Baltimore had finished speaking," one of Gallo's associates recalled, "Bob came right back up and said, this is what we're going to work on."

Baltimore and Temin had found reverse transcriptase in cancer cells taken from mice and chickens, but if the human cancer virus program was going to go forward somebody would have to find it in human cancer cells. Within a few months Gallo had obliged, publishing a paper reporting the discovery of reverse transcriptase in human leukemia cells.

It looked at first like another historic breakthrough, important enough to put Gallo on the same program with Baltimore and Temin at the Nobel ceremony in Stockholm. But no one who attempted the same experiments could reproduce Gallo's results, and reproducibility is the acid test of science.

Throughout the early 1970s Gallo continued to refine his test for reverse transcriptase, but his periodic reports of new detections of the enzyme in human cancer cells were met with varying degrees of skepticism by his fellow scientists. If Gallo could keep finding reverse transcriptase in human cancer cells, they wondered, why couldn't he find the retrovirus that was producing it?

It was a reasonable question and, in January of 1975, Gallo and a National Cancer Institute colleague named Robert Gallagher announced that they had found the first human cancer retrovirus, called HL-23, in some leukemic blood cells from a woman in Texas. Despite the scientific convention that frowns on announcing important breakthroughs in the news media, reports of Gallo's discovery were in the newspapers before his landmark article was in print. "I got up one morning and read the headlines of the Washington Post," Gallagher recalled. "I was shocked to find that he'd been talking to the press."

It was a great moment while it lasted—"a great Eureka," Gallo called it at the time—but it lasted for only a year. A group of American and British virologists, attempting to confirm his historic find, discovered that the first human cancer virus wasn't human at all but a cocktail of monkey, ape and baboon viruses.

Gallo tried to explain his error by suggesting that the Texas woman had somehow been infected with the baboon virus, but there was really only one conclusion to be reached: Gallo's culture had been contaminated in his laboratory. Gallo first attributed the contamination to "sabotage by my enemies"; now he says, "Who the hell knows?"

Whatever happened to HL-23, by the time it was discredited most of the bright young researchers who had enlisted in the hunt for a human cancer retrovirus had concluded there probably was no such thing, at least not in solid, or tumor, cancers of the breast, colon and lung, and they were the most common.

As Gallo's erstwhile colleagues departed the NIH campus for academia and private industry, they joked that human tumor viruses might as well have been called "human rumor viruses." Now that viruses were passe, the smart money in cancer research was betting on so-called "cancer genes," pieces of defective DNA that somehow trigger the cancerous proliferation of ordinary cells. The cancer crowd also joked about HL-23. Gallo remembers more than one occasion when, preparing to speak at a scientific meeting, he was greeted with derisive laughter.

The question of whether viruses might be involved in blood cancers like leukemias was technically still open. In 1978, scientists in the Netherlands not only detected reverse transcriptase but also photographed what looked like a retrovirus in cells from several patients with an uncommon kind of T-cell cancer known as mycosis fungoides.

But the Dutch weren't able to say much about the new retrovirus, or even whether it was actually responsible for their patients' disease. In order to prove that the virus was causing mycosis fungoides they would need to find it in a much larger number of patients, and they couldn't. "We tried," recalled Elizabeth van der Loo, who as a young graduate student was chiefly responsible

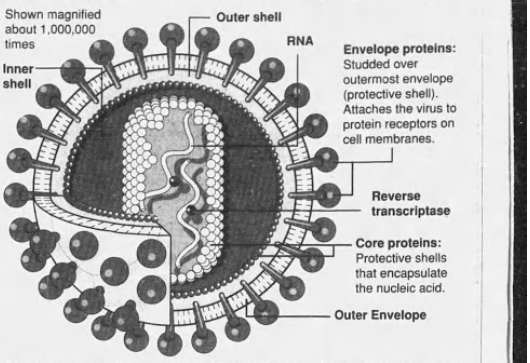
Anatomy of a Human Immunodeficiency Virus (HIV)



RNA (ribonucleic acid): Important in protein synthesis and genetic transmission and is found in all cells and many viruses. Nucleic acids are the chemicals that control cellular heredity and function. All viruses consist of nucleic acid, either RNA or DNA (deoxyribonucleic acid), but never both.

Reverse transcriptase: An enzyme that acts as a biological trigger, stimulating the formation of DNA on a template of RNA in certain viruses composed of RNA, a process crucial to the retrovirus life cycle. The flow of information from RNA to DNA is the reverse of the normal information pathway, hence the name.

Proteins: The tool kit and framework of all cells and components of viruses. They can also serve as enzymatic catalysts that cause or accelerate chemical reactions. Proteins are polymers, long strings of amino acids attached to one another like beads in a necklace to form a larger, more complex molecule.

How subtle invader destroys cells that control the body's defenses

The virus that causes AIDS is one of hundreds that inhabit humans, animals, insects, plants—even bacteria. Viruses can take many sizes and shapes. Some are harmless; others cause disease ranging from smallpox, polio and measles to yellow fever, herpes and flu.

Viruses are very small—a hundred times smaller than even bacteria. And, while some are more complex than others, they are among the simplest things on earth: a tiny shred of genetic information tucked inside a protein shell and sometimes covered with an envelope of fatty material. Viruses are not alive. They can reproduce themselves, but only after they have invaded the cells of their preferred host and gained control of the cells' genetic machinery.

Once inside the cell the virus begins its reproductive process, spewing forth new virus particles at such a rate that the cell is destroyed. A single virus can reproduce itself thousands of times in a matter of hours, which is why people who contract most viral diseases become ill a short time after infection.

All the diseases that have been linked to viruses result in some way from the process of infection. The leukemia virus called HTLV-1 infects mainly helper T-cells, the controllers of the human immune system, and causes them to multiply out of control. The AIDS virus infects the same kind of cells but kills them, leaving the body vulnerable to a variety of potentially lethal infections.

The genetic material of many viruses is DNA, a chain of molecules called nucleotides strung together in a sequence that spells out the life-code for every living thing from people to potatoes. When a DNA virus infects a cell, it begins the reproductive process by employing its cousin, RNA, to assemble amino acids into the catalytic proteins, called enzymes, that it needs to construct more copies of itself, and then to assemble the structural proteins that form new virus particles.

The genetic codes of some viruses, like the AIDS virus, are written not in DNA but in RNA. Such viruses, called retroviruses, use an enzyme called reverse transcriptase to copy their original genetic RNA into a complementary strand of DNA that inserts itself into the much larger strand of human DNA in the host cell.

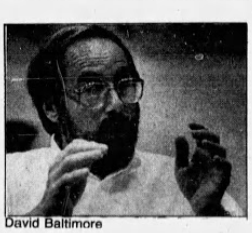
A historical look at AIDS research from 1970 to 1987

JUNE 27, 1970: **Howard Temin** and **David Baltimore** discover reverse transcriptase in cancer cells from mice and chickens.

DEC. 5, 1970: **Robert Gallo** first reports finding reverse transcriptase in human leukemia cells. The report is viewed with skepticism by fellow scientists.

JAN. 31, 1975: **Gallo** announces the isolation of the first human cancer virus, HL-23. It later proves to be a cocktail of monkey and baboon viruses.

SEPTEMBER, 1977: Japanese scientists report an epidemic of disease they call adult T-cell leukemia (ATL) in that country's southwestern provinces.



David Baltimore

1979: Dutch researchers report finding and photographing retrovirus particles in patients with a kind of cancer called mycosis fungoides.

MARCH, 1980: NCI's **Adi Gazdar** reports the establishment of the permanent T-cell lines HUT78 and HUT102, the latter from a 27-year-old mycosis fungoides patient named **Charles Robinson**.

DECEMBER, 1980: **Bernard Poiesz** and **Frank Ruscetti** report the isolation of the first human cancer virus, HTLV, from **Charles Robinson's** cells.

MARCH 24, 1981: At a meeting in Kyoto, Japan, **Gallo** learns **Yorio Hinuma** has found antibodies to a viral antigen in 100 percent of Japanese patients with ATL. **Gallo** tells the group he has found antibodies to HTLV in "some" ATL patients.

JUNE, 1981: UCLA's **Michael Gottlieb** reports first six cases of what will later be called AIDS.

FEB. 19, 1982: **Gallo** publishes data showing antibodies to HTLV in blood from Japanese ATL patients, suggesting his virus may be the same as that detected by the Japanese.

How the AIDS retrovirus attacks the helper T-cell

1. AIDS virus enters the human circulatory system.

2. Virus specifically targets a cell in the human immune system, known as the helper T-cell. It attaches itself to a special receptor that is on the outer wall of the T-cell.

3. Virus is absorbed into the host cell, shedding its outer shell and releasing its own genetic code (RNA) along with the reverse transcriptase enzyme.

4. Enzyme uses the viral RNA to manufacture a DNA copy of itself.

5. Viral DNA inserts itself into the host cell DNA, where it may lie dormant for up to 10 years.

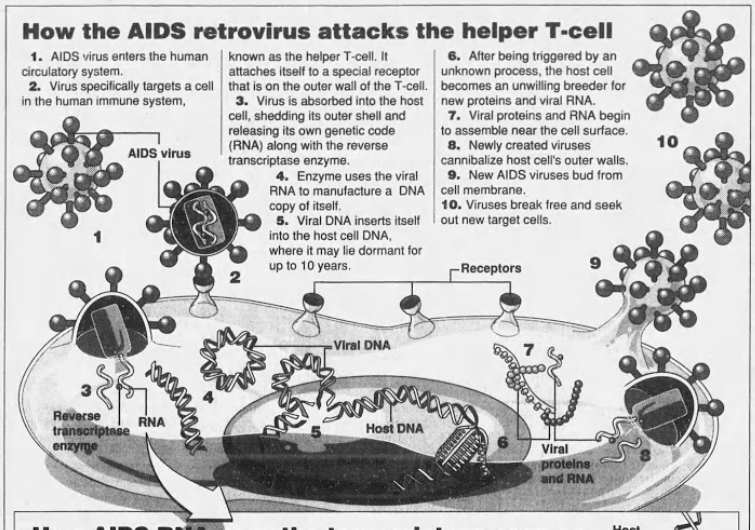
6. After being triggered by an unknown process, the host cell becomes an unwilling breeder for new proteins and viral RNA.

7. Viral proteins and RNA begin to assemble near the cell surface.

8. Newly created viruses cannibalize host cell's outer walls.

9. New AIDS viruses bud from cell membrane.

10. Viruses break free and seek out new target cells.



How AIDS RNA uses the transcriptase enzyme

Normal DNA contains the nucleotides adenine, cytosine, guanine and thymine (A,C,G and T). Instead of thymine, RNA uses uracil or U.

1. The reverse transcriptase enzyme uses the AIDS virus single-strand RNA as a template to create a complementary strand of DNA from nucleotides found in the host cell. RNA also has a slightly different composition of the sugar phosphate backbone that holds the nucleotides together.

2. This creates an RNA-DNA double-helix.

3. A DNA copy of the RNA half is made, which then replaces it.

4. The new DNA double helix strand contains the AIDS virus coding.

5. The viral DNA inserts itself into the host cell's DNA, directing the host cell to produce more RNA and proteins to create new AIDS viruses.

for the discovery. "But in Holland there are not so many patients with mycosis fungoides."

Gallo's lab, which in the wake of the monkey virus contamination had all but stopped looking for a human cancer virus, had been reduced to publishing papers on the biochemistry of the blood. The initiative to renew the search came from a young physician named Bernard Poiesz who joined the lab in the fall of 1978 as a postdoctoral fellow.

Poiesz had elected to work under one of Gallo's associates, a young cell biologist named Frank Ruscetti, who had just made a great leap forward in the laboratory technique for growing T-cells. With another Gallo assistant named Doris Morgan, Ruscetti had discovered and isolated the protein, now called Interleukin-2, that the human immune system uses as a biochemical signal to encourage T-cells to divide and multiply in response to an infection.

The first year of Poiesz's fellowship had been spent with cancer patients, and he had seen a number with the T-cell cancers that are known as lymphomas. What he wanted, he told Ruscetti, was to continue looking at cells from such patients in hopes of finding a clue to what caused their disease.

The research from Holland had not yet been published, and Poiesz had no real reason to expect to find that lymphomas were being caused by a human cancer virus. But he had learned the art of testing cells for reverse transcriptase as a medical student at the University of Pennsylvania, and "it seemed reasonable to look, because we knew how to look."

Among the first cells Poiesz got to look at were some taken from the lymph node of one of his former patients, a 28-year-old Alabama man named Charles Robinson. "I actually wound up being the fellow that admitted him for the lymph node biopsy," Poiesz says, "not realizing what that lymph node biopsy was going to get us all into."

Robinson had been diagnosed as having mycosis fungoides, the same kind of T-cell cancer as Elizabeth van der Loo's patients. Before Robinson died, however, another cancer institute researcher named Adi Gazdar mixed some of Robinson's cancerous T-cells with Frank Ruscetti's Interleukin-2. The result was a continuous T-cell culture called HUT102, in which Robinson's leukemic T-cells would go on dividing and multiplying in the laboratory long after he was dead.

When Poiesz and Ruscetti began looking at the cells from HUT102 shortly before Christmas of 1978, they found measurable levels of reverse transcriptase. But Poiesz was aware that scientists in Gallo's lab and elsewhere claimed to have detected reverse transcriptase in human cancer cells before. There had been so many false alarms, Poiesz recalled, that "in order for something to be considered interesting there had to be an extraordinary amount of reverse transcriptase."

Because Robinson's cells were showing only a small amount of enzyme activity, Poiesz said, "many people were very skeptical. But I had done enough reverse transcriptase assays on normal T-cells to recognize that if there was a little bit of production, that's all you needed to see to be interested."

In fact, Poiesz and Ruscetti were more than interested. Over the next few months they worked night and day, growing huge quantities of Robinson's cells and trying to isolate, purify and analyze the virus they appeared to contained. "I grew 120 liters of it and saw that it didn't behave like anything else," Poiesz said, "yet it clearly was a retrovirus. We knew that we had stumbled onto something that was different."

Their main concern was that whatever virus was reproducing in Robinson's cells might be one of the many animal retroviruses that were being grown elsewhere in the same building—and which, in a bizarre reprise of the HL-23 fiasco, might have somehow contaminated their cultures. Painstakingly, the two researchers checked their cultures for every one of the dozens of known animal retroviruses. When there were no more animal viruses left, Poiesz recalled, "We knew we had something."

But they were unable to give the good news to Gallo, who was on an extended trip out of the country. "I'd proceeded to do the additional work while he was away," Poiesz said. "He was gone for a couple of months." When Gallo found out that what appeared to be the first human cancer retrovirus had been isolated in his lab, it was in a conversation with another scientist at a backyard cocktail party in Bethesda. "He had just come home that weekend," Poiesz recalled. "I was supposed to have a meeting with him on Monday. I must say he was a little ticked at us."

Considering that he had spent much of the previous decade looking for the first human cancer virus and then enduring the derision of other scientists after he mistakenly claimed to have found it, Gallo's annoyance was understandable to Poiesz. "He was a bit astounded that this had happened," Poiesz said, "because they had tried so long to find a retrovirus. Some very skilled people had tried it, and here was a junior member of the team, a postdoc, and in the first month of working he finds the human retrovirus. That seemed too lucky to be true."

To top it off, Poiesz and Ruscetti had been lucky not just once but three times out of three, finding what looked like the same new virus in a Caribbean islander and in a man from Boston. By then, another researcher in Gallo's lab recalled, there was "quite an uproar about the rest of the people in Gallo's lab not having been included in the discovery. Basically, they had opted out because they didn't believe Bernie in the first place. Then at that point Gallo kind of took over."

In December of 1980, a paper reporting the isolation of a new human retrovirus from a patient identified only as "CR" appeared in the distinguished monthly Proceedings of the National Academy of Sciences. The paper's first author was Bernie Poiesz, with Frank Ruscetti second. Gallo's name was last.

Gallo has called the discovery of HTLV "one of the most exciting stories of 20th Century biology," and it soon earned him informal recognition as "the father of human retrovirology." In keeping with scientific tradition, Gallo also gave the new virus its first name: human T-cell lymphoma virus.

What Gallo's associates remember most, however, was his disappointment that the new virus had not been found in a patient with leukemia, but in one with a lymphoma, mycosis fungoides, which affects far fewer people. "We argued whether it should be lymphoma or leukemia," Poiesz said. "I wanted to not even say it was a human virus until we knew for sure, but HTLV is the name that he wanted it to be."

As would have been true of any report of any new human virus, particularly one announcing the first human cancer retrovirus and especially one from the lab where the HL-23 debacle had occurred just five years before, the HTLV paper attracted a great deal of attention. But once the initial excitement had begun to fade, it became clear that the most important questions remained unanswered.

Although its name implied that the new virus was the cause of T-cell lymphoma, or at least played some central role in the disease, there is no way to be sure a virus isolated from a single patient, or even three such patients, is anything more than a laboratory curiosity. "It was clearly very different and we clearly had it in three humans at that point in time," Poiesz says. "But we hadn't proven that it had caused disease, nor did we at that point have any idea about what was really going on."

When Poiesz and Ruscetti began testing other mycosis fungoides patients for the virus, they couldn't find a single person who was infected, which meant that whatever the virus did, it probably didn't cause mycosis fungoides. "We were striking out," Poiesz says. "At that point it hadn't dawned on us that there might be an epidemic somewhere else in the world."

There was such an epidemic, but it was a long way from Bethesda and it involved a different disease. In the fall of 1977, a year before Bernie Poiesz arrived in Gallo's lab, a team of Japanese medical scientists in Kumamoto had published the first report, in the American journal Blood, of a newly recognized disease they called adult T-cell leukemia, or ATL for short.

A handful of other diseases had previously been discovered that involved the cancerous proliferation of T-cells, but these Japanese cases were unlike anything seen before. Not surprisingly, the urgency to find out what ATL was all about was greatest in the country where its victims lived. Within a few months, a researcher at the Okayama Cancer Institute named Isao Miyoshi had succeeded in growing T-cells taken from a 69-year-old man who had died four months after coming down with ATL.

From the way the old man's cells behaved in the lab, Miyoshi concluded that there must be something in his culture that was being transmitted from one cell to another. The most logical thing was a virus; and because the cells were producing reverse transcriptase, it seemed likely to be a retrovirus. When Miyoshi sent some of the cells to Yorio Hinuma, the eminent Kyoto virologist, Hinuma could see retrovirus particles under an electron microscope.

Three months after Poiesz and Ruscetti's paper electrified the scientific community, Gallo traveled to Kyoto to attend a hastily called meeting to discuss recent developments in human retrovirology. A short time before, Gallo's lab had received some blood samples from Japanese ATL patients sent by another Kyoto researcher, Yohei Ito, who had heard about Poiesz's paper and who wondered whether this new virus called HTLV might have something to do with ATL.

When Gallo's turn came to speak, he reported that some of the blood samples he got from Ito had contained antibodies that reacted with his virus—an indication that some of the Japanese ATL patients might be infected with a virus like HTLV-1. But Hinuma had done some similar experiments, and his results were more conclusive.

Hinuma had mixed Miyoshi's cells with serum, the liquid component of blood that remains after the cells have been removed, that had been taken from a number of patients with ATL. In each case, when the cells were placed under an ultraviolet light, a high percentage of them lit up—evidence that the serum from every single patient, not just some, contained antibodies that were reacting with something foreign in Miyoshi's leukemia cells.

Although he was too cautious to call it a virus at the time, the "something foreign" proved to be the retrovirus Hinuma had photographed. The Japanese named it ATLV, for adult T-cell leukemia virus.

"The Japanese work was driven by studying the pattern of the disease. Gallo's work was driven by coming across this virus and being unaware of ATL," says Robin Weiss of the Institute of Cancer Research in London, a noted retrovirologist and a coauthor of the definitive textbook on human retrovirology.

"Hinuma did that beautiful work," Weiss said. "I think he deserves real credit for that. I think Ito probably deserves the credit for saying this new virus of Gallo's might have something to do with this disease. I'd give Miyoshi the fine credit. Miyoshi's a modest and quiet man; he's continued to do super work in the field."

Except for the Japanese, Gallo's HTLV might well have remained a virus in search of a disease. But now that the Japanese patients were known to have antibodies to both Gallo's virus and to ATLV, it was important to know whether the two viruses were the same. The best way to find out was to crack their genetic codes—literally, to take them apart, identify their genetic building blocks one by one, and then compare them side by side. Although Gallo's assistants struggled with the problem for months, they were unable to clone their virus, a crucial step in breaking its code.

"To be honest," Bernie Poiesz recalls, "the people that were capable of cloning back at NIH were not all that interested. They didn't fully believe the story and they had other priorities. The Japanese worked very fast and very hard. They beat us to the punch."

In the summer of 1983, when scientists in Tokyo published the genetic sequence of ATLV, they managed even without a comparable sequence of HTLV to determine that the two viruses were "very similar." Later experiments appeared to show that the two viruses were in fact the same, which led to a final question: How could the same virus that caused adult T-cell leukemia in Japan have been discovered in Charles Robinson, a patient with mycosis fungoides who had never been anywhere near Japan?

The question became more compelling after Yorio Hinuma, in collaboration with Abraham Karpas, a retrovirologist at Cambridge University in England, reported that every mycosis fungoides patient they tested was negative for antibodies to ATLV. Not long afterward, Gallo and the cancer institute's clinicians concluded that Robinson had not died from mycosis fungoides but from a new kind of T-cell cancer that was much more like adult T-cell leukemia.

In scholarly articles recounting the discovery of HTLV, Gallo began referring to Charles Robinson as a patient with "leukemia-lymphoma," and then simply as someone who had died of adult T-cell leukemia. Although its initials stayed the same, the name of Gallo's virus changed as well: from human T-cell lymphoma virus, to human T-cell leukemia-lymphoma virus, and finally to human T-cell leukemia virus.

With the discovery of HTLV, the humiliation of HL-23 was nearly forgotten—and so, at least by Gallo, were the early contributions of the Dutch and the Japanese. Before their first paper on HTLV was published, Poiesz said, he and Ruscetti had given copies of both the Van der Loo paper from Holland and the one reporting the ATL epidemic in Japan to Gallo, with the suggestion that he might want to mention them in a footnote. He didn't.

In one scholarly article he authored later on the discovery of HTLV, Gallo awarded the Japanese two footnotes out of 85. In another, he gave his own lab credit for having established the link between the virus and adult T-cell leukemia, which was really something Hinuma and Miyoshi had done. To a colleague who asked for recommended reading on HTLV, Gallo sent a list of his own publications. "Much of the additional work," he wrote, "most of it from Japan, is really not terribly relevant. There are a few publications from Holland but they do not say anything particularly new."

When Gallo won his first Lasker prize in November of 1982, for the discovery of HTLV, there wasn't any mention of Bernie Poiesz or Frank Ruscetti. "When people talk about HTLV, it's always Gallo, Gallo, Gallo," an NIH scientist says. "You don't hear Bernie Poiesz's name, and you never hear Frank's name."

After Poiesz's postdoctoral fellowship was over he moved to Syracuse, where he now heads the division of hematology-oncology at the State University of New York Medical Center. When he used Gallo as a reference in applying for a grant to continue his work with HTLV, Poiesz recalls that Gallo responded with an unflattering letter.

"He basically wanted to make sure that he was the major player as the theme of HTLV worked its way out into the world," says Poiesz, who did go on working with HTLV. "I think his competitive nature was such that for some reason there was a false sense of concern that I might do well with it."

From his vantage point in Upstate New York he has watched while his former boss has taken the center stage of science. "There's many different reasons why people associate Bob Gallo's name as the discoverer of HTLV," he says. "I can't change how people perceive it, or how people presented it to the media. The only thing I can do is do my work. I spent many, many nights in that laboratory. The moment of discovery was mine."

In the years immediately following that discovery, Frank Ruscetti fared less well. "Frank's a relatively strong person and Bob's a pretty strong person," says one man who knows both of them. "There was a particular enmity between them for some time. There was a pyramid and Bob Gallo was the boss."

Before long Ruscetti was not only out of Gallo's lab but out of science altogether. It was nearly two years before he would find his way back in, at a National Cancer Institute satellite facility in Frederick, Md., where he is still

employed. "My battles with Gallo were legendary," Ruscetti says, "but I won't talk to you. I just keep my mouth shut and try to do science."

When Gallo wrote the official history of his research on AIDS and human retroviruses, he recorded that the first human cancer virus, HTLV, had been discovered by "Gallo, Poiesz and coworkers." Asked about the history of that discovery last year, Gallo replied, "I think I've forgotten more than Poiesz and Ruscetti ever knew, times 10."

3 'You have to let Jean-Claude speak'

In the spring of 1983, while Bernie Poiesz was still enjoying the memory of a postdoctoral fellowship that had produced an almost unheard-of 11 major papers, and while Frank Ruscetti was still looking for work, Robert Gallo was channeling the search for the source of AIDS in the direction of the leukemia virus they had discovered.

But even as Gallo was promoting the virus, which he now called HTLV-1, in interviews and letters to his colleagues as the "leading candidate" for the cause of the AIDS epidemic, experiments in his own laboratory were producing persuasive evidence that HTLV-1 had nothing to do with AIDS.

At Harvard, Max Essex was finding ever-higher percentages of AIDS patients positive for what he said were antibodies to the leukemia virus. But Gallo's assistants had also begun testing AIDS patients' blood samples with a more specific test, one that measured antibodies to the virus itself, not to a mysterious protein on the surface of virus-infected cells, and they were obtaining very different results.

A few weeks before Gallo's papers on the possible link between the leukemia virus and AIDS were published in Science in May, 1983, one of Gallo's assistants sent him a note reporting that only 17 AIDS patients "out of a much larger number tested" had so far proven antibody-positive. The following month, Gallo acknowledged in a memo to a senior cancer institute official that, despite Essex's impressive numbers, his own lab was finding that most AIDS patients were not infected with HTLV-1.

Gallo's staff had also detected the leukemia virus itself, not just antibodies to the virus, in a small number of AIDS patients like Claude Chardon. But except for the four detections that Gallo reported in Science and a handful of others, efforts to find the virus in other AIDS patients had been unavailing. Lee Ratner, a molecular biologist who joined Gallo's lab as the hunt for HTLV-1 in AIDS patients was gathering speed, recalled that Gallo's assistants had looked for the virus in "something like a hundred" AIDS patients and that all of them were negative.

Gallo didn't report the low numbers of AIDS patients who had antibodies to the leukemia virus or who were infected with the virus itself. As the negative data piled up behind the scenes, Gallo continued to make the case for his virus in public. "The evidence is certainly accumulating," he told the Journal of the American Medical Association in June of 1983, that HTLV was "the best lead yet found" for the cause of AIDS.

In addition to overseeing the other operations of his cancer laboratory, in the spring of 1983 Gallo was spending increasing amounts of his time on AIDS—so much that, in April, he complained in a letter to a Japanese scientist that "the pressure on me is unusually severe." The reason, he said, was that he had just accepted an "additional new responsibility" as scientific director of a new cancer institute task force on AIDS.

When the task force held its first formal meeting in July, Luc Montagnier, chief of cancer virology at the Pasteur Institute in Paris, flew in to attend. In response to an appeal from Gallo, Montagnier brought a tiny vial containing a sample of the virus the French believed to be the cause of AIDS. In April, the French had sent Gallo a tiny vial of viral DNA. Gallo said it hadn't been enough. "We desperately need more DNA," Gallo wrote Montagnier a few days later. "The data is critical for you, us and the field so please do everything possible to get a good amount of DNA to us as soon as possible."

To the three dozen members of the task force Gallo said what he had been saying in public, that his leukemia virus made a "very attractive" candidate for the cause of AIDS. But Montagnier had brought data on new isolates of the French virus taken from other patients with AIDS, and also some photographs of the virus he hadn't published in Science. "I was reluctant to show them in the paper," Montagnier explained later, "because people would say it was just a viral contamination with something else."

The new pictures were viewed with a careful eye by Matthew A. Gonda, the chief of the cancer institute's electron microscope facility in Frederick, Md. Gonda had recently written a paper on a class of animal retroviruses known as lentiviruses, slow-acting retroviruses that until then had been found only in goats, horses and sheep and whose barlike core is readily distinguishable from the disc-like core of HTLV-1.

It looked to Gonda like the virus the French were now calling LAV had to be a lentivirus too. When Gonda wrote a memo to that effect, recalled Berge Hampar, the former general manager of the Frederick facility, "Gallo was really furious. The last thing he wanted to hear was that the French had a lentivirus, because if it was lenti that meant it wasn't HTLV. He called Gonda at home, ranting and raving. He screamed at him for an hour."

Scientific meetings at Long Island's venerable Cold Spring Harbor Laboratory have a special cachet. Apart from the laboratory's picturesque waterside setting, it has a history of producing good science. Its reputation derives largely from the fact that its director is James D. Watson, the American biologist who, with Francis Crick, solved the mystery of the double helix—the structure of DNA.

When Gallo and Essex were asked to organize an important conference on HTLV at Cold Spring Harbor for mid-September of 1983, they included a special forum on the known links between the leukemia virus and AIDS. Montagnier was among those invited to Cold Spring Harbor, and he had a good deal to say.

All summer the Paris group had been working with success to firm up the connection between its new virus and AIDS, and it had made some significant advances. When Montagnier learned he had been given just 15 minutes to speak, he protested. "I am asking you," he wrote to Gallo, "to allot me 30 minutes, and possibly not at the very end of the meeting."

The Cold Spring Harbor conference opened on the morning of Wednesday, Sept. 14, with a welcoming speech by Essex and an introduction by Gallo. For the rest of that day and most of the next, a succession of scientists reviewed various aspects of their work on Gallo's leukemia virus and its odd new cousin, HTLV-2.

When the session on AIDS began late Thursday afternoon, Essex began with the report that he had now detected leukemia virus antibodies in up to 70 percent of AIDS patients. He was followed by Gallo, whose talk highlighted "the possibility that HTLV plays an important role in the origin of AIDS." The next-to-last speaker was Montagnier, who had been given 20 minutes to speak instead of the half-hour he asked for and who was still at the end of the program. By the time he took the podium, many of those at the meeting had already left.

Since the beginning of the year, Montagnier began, the new French virus had been identified in a total of seven patients besides BRU, the fashion designer from whom it was first isolated. The French, moreover, had now found their virus in at least one member of every group in which AIDS seemed to be prevalent: three homosexuals, a hemophiliac and a Haitian.

They had also developed a test for antibodies to the virus. Since July, Francoise Brun-Vezinet, the physician who had delivered a piece of BRU's lymph node to the institute in January, had been growing the French virus in a special room in the basement of the Pasteur. The purified virus had been used to test for antibodies in dozens of AIDS patients' blood samples, including some that had been sent to Paris by doctors in New York.

The Pasteur tests, Montagnier said, were showing that more than 60 percent of patients with pre-AIDS, and nearly 20 percent of those with AIDS, had antibodies to the French virus. The same patients, however, had tested negative for HTLV. The two viruses, he said, seemed to be "clearly distinct." They didn't react biochemically, and when the French virus was looked at under an electron microscope it had an entirely different shape. The only other virus that resembled it at all was a lentivirus that caused infectious anemia in horses.

By all accounts, it was a dramatic moment. Montagnier was telling Gallo, and in front of many of his closest colleagues, that for the better part of a year he had been leading science down the wrong road. According to several of those present, when the time came for Montagnier to entertain questions Gallo rose to the attack, suggesting that the measurements of reverse transcriptase activity by the French had been flawed and that they hadn't isolated a retrovirus at all. "He told him it was terrible science," said a scientist who was there, "that there was no way it could be true."

"I went up to poor Montagnier afterwards," another scientist recalled. "He was sitting in the corner. He looked like he'd been beaten over the head with a sledgehammer. I said, 'The data looks good, I'm sure you've probably got it, don't take to heart what these guys have said to you.' "

Gallo now regrets his treatment of Montagnier. "He was definitely, definitely hurt and it certainly hurt our relationship badly," he told The Tribune. "I wouldn't do that again."

Montagnier's talk had gone far beyond the BRU paper in Science four months before, but many of those at Cold Spring Harbor were still not convinced by his data. For a few, however, the talk provided their first real understanding of the depth and importance of the French research on AIDS. The Science paper, recalled the British retrovirologist Robin Weiss, "turned out to be a seminal paper, but it didn't convince the world that this was the virus. His Cold Spring Harbor paper made me take that first one much more seriously."

Bernie Poiesz was in the audience that day. Like Gallo and Essex, Poiesz had been looking for evidence that the leukemia virus had something to do with AIDS, and he remembers thinking after Montagnier's presentation that the French might be right after all. "The data seemed to make sense," Poiesz said. "He obviously didn't have it fully developed, but he had gone a substantial way and it was plausible to me that they had found something that was different."

Impressive as the French data were, researchers who hadn't attended the Cold Spring Harbor meeting remained mostly unaware of the latest findings from Paris. One was the University of California's Jay Levy. In early October, in Paris for his brother's wedding, Levy stopped by the Pasteur to say hello. It was not until then, he recalled, "that I realized they did not have HTLV" but something completely different.

As an AIDS-causing agent, Levy said, the French virus "was almost too good to be true." It grew in the same helper T-cells that AIDS patients lacked, Levy said, and it killed them. "I came back to the hotel room and I told my wife, 'Sharon, I've been looking for this virus and I think they've found it.' But if I hadn't gone to see them I never would have known."

Within a few weeks, Levy would isolate the AIDS virus in his San Francisco lab, but he would not publish his discovery for several months after that. Levy wanted to make sure the virus, which he would call ARV, for AIDS-related virus, could survive the acid treatment used in the preparation of the clotting factor that keeps hemophiliacs from bleeding to death. If it couldn't, it was obviously the wrong virus and Levy would have to look somewhere else.

A few days after the September meeting at Cold Spring Harbor, one of Gallo's assistants sent him the latest draft of the still-unpublished paper reporting that only 8 percent of the AIDS patients they had tested had antibodies to HTLV-1. "Not sure he will want to publish on AIDS at this time," the assistant wrote to one of her colleagues, "but we'll see."

While Gallo pondered whether or not to publish, the French were having trouble getting their latest research into print. Their Science paper had shown that the French virus infected T-cells, but not which kind of T-cells. Since then, Paris immunologist David Klatzmann had proven that the virus had a particular affinity for infecting—and killing—the helper T-cell, precisely the same cells AIDS patients didn't have enough of.

Klatzmann's discovery made the most convincing case yet that the French virus played a critical role in the disease. Had it been published, Robin Weiss said later, "it would have added some weight, because it would have said this odd virus we have selectively grows in and kills the kinds of cells that disappear from AIDS patients."

In trying to determine the attraction of the virus for helper T-cells, Klatzmann had used blood samples taken from a young hemophiliac who had been injected regularly for years with a clotting factor known as Factor VIII, some of which had been made from blood tainted with the AIDS virus. What was significant was that, unlike all the other patients in whom the French had found the virus, this young man was perfectly healthy.

In the summer of 1983, no one suspected that infection with the AIDS virus would be as widespread as it is. Fewer than 2,000 Americans were then ill with the disease, and many doctors assumed that, as with most contagious diseases, illness set in a short time after infection. By isolating their new virus from someone who was still healthy and had been infected for some time, the French had discovered the phenomenon of the "healthy carrier," those infected but symptom-free individuals who, by unwittingly infecting others, had spread the virus through large populations of gay men and heroin users.

When Klatzmann and the Pasteur group sent a paper describing the affinity of the AIDS virus for helper T-cells to Nature in the summer of 1983, the paper was summarily rejected. One of the journal's reviewers had only a few technical criticisms, but the other dismissed it out of hand. If what the French were saying was true, the second reviewer wrote, it would be a very important paper. He just didn't think it was true—it sounded to him like what the French had was a mouse virus contaminant.

The authors quickly resubmitted their paper to an American journal, the Proceedings of the National Academy of Sciences. One of that journal's reviewers thought the paper should be published forthwith, but the second reviewer never replied. When Klatzmann encountered the man at an AIDS conference in Atlanta two years later, he recalled, "he told me that he had been too busy."

While many of those attempting to treat AIDS patients were under the misapprehension that Gallo's leukemia virus, or one very much like it, was the cause of AIDS, the French continued to try to make their voices heard. Because of the difficulties they were having in publishing their papers, the French decided to use important scientific meetings like the one at Cold Spring Harbor to spread the word of their discoveries.

But when Klatzmann presented his unpublished data to a meeting of the New York Academy of Sciences in November, his talk didn't produce many headlines. "The journalist from the New York Native [a weekly newspaper with a mostly homosexual readership] called and he did interview me, actually," Klatzmann recalled. "I was also interviewed by Channel 13," the public broadcasting station in New York, "but I was told later that they took off my part."

Despite the ongoing work in Paris, Gallo's human leukemia virus was still the hottest thing in virology. But even as Gallo was adding the American Cancer Society's medal of honor to his prizes and awards, the case for HTLV-1 as the cause of AIDS was beginning to collapse under its own weight. According to the minutes of the November meeting of Gallo's AIDS task force, that month's discussion focused on what to do about "the continuing problem" posed by the still-unpublished data showing that very few AIDS patients were infected with the leukemia virus.

Part of the problem was that the negative data were no longer coming only from Gallo's lab. One task force member had found only a single AIDS patient out of 59 positive for antibodies to the Gallo virus, and a handful of scientists outside NIH were now questioning Gallo's thesis in public. Some weeks earlier, a Boston University researcher named Paul Black had sent a letter to the New England Journal of Medicine suggesting that Gallo's leukemia virus was "unlikely to be in itself the cause" of AIDS. In an interview with the Associated Press, Black dismissed Gallo's research on the connection between AIDS and the leukemia virus as "hype."

Gallo was not pleased. "There are people who were writing letters at that time in the New England Journal saying we were nuts," Gallo recalls. "Paul Black. I know Paul, I regard him as a colleague and friend and I didn't understand why he wrote it. I called him up on the telephone and argued with him."

Although Black's objections were founded on intuition, a few other labs had been compiling the same sort of negative antibody data that Gallo had in his lab. But it was proving as difficult for the others as for the French to find their way into print.

Sometime in 1981 a Manhattan physician named Joseph Sonnabend first began seeing a few mysterious cases of what would later be called AIDS. Like other doctors in New York and San Francisco, Sonnabend was interested in learning as much as possible about the disease that was killing his patients. When Gallo began suggesting two years later that HTLV-1 played an important role in AIDS, Sonnabend started taking blood from his patients to be tested for antibodies to Gallo's virus.

The tests were conducted by Shinji Harada, who was spending a year at the University of Nebraska and who already knew a lot about the leukemia virus. Before coming to Omaha, Harada had investigated on his own the idea that the virus might have something to do with AIDS, but he hadn't found any connection.

When Sonnabend's blood samples arrived in Omaha, Harada ran the same tests again, and with the same results. "AIDS patients had no antibody against HTLV," Harada says.

Just to be sure, Harada forwarded some of the same samples to scientists in two other laboratories. One was Yorio Hinuma, the Kyoto University virologist who established the first link between Gallo's new human retrovirus and adult T-cell leukemia. The other was Abraham Karpas, a retrovirologist in the department of hematological medicine at Cambridge University in England. Both Hinuma and Karpas confirmed Harada's results in short order.

When the Sonnabend group wrote up its findings and sent the paper off to several major journals, none of them was interested. Sonnabend had recently taken on the task of editing a new journal devoted exclusively to AIDS, and in his capacity as editor Sonnabend decided to publish his own paper. "I toned it down somewhat," he recalls; "which I sort of regret now. I even added a sentence at the end, to the effect that maybe the difference between our results and Gallo's could be attributed to the different geographical ori-

gin. But I was just being polite."

In December of 1983, Gallo finally sent his negative findings on HTLV-1 and AIDS to the Lancet. At first glance the paper looked like a refutation of what he had been saying for the last year about possible links between the leukemia virus and AIDS, but it was much more subtle than that. In addition to reporting the mostly negative antibody data, the Lancet paper encouraged speculation that the cause of AIDS might be an undiscovered near-relative of HTLV-1. "There is no need," the paper cautioned, "to assume that members of the HTLV family are limited to two strains."

Max Essex had recently found a slight genetic variation in the feline leukemia virus that he said turned it from a cancer virus into a cell-killer, and now Gallo was suggesting that the AIDS agent might be a similarly mutant form of HTLV-1. The "undiscovered relative" theory was attractive for a number of reasons. Among other things, Gallo had never been able to explain the absence of AIDS in Japan, nor how a virus that caused the uncontrolled multiplication of white blood cells could also be responsible for the disappearance of those same cells.

As it happened, researchers in Gallo's lab had recently discovered just such a minor variant of HTLV-1 in an American homosexual with AIDS. It was very closely related genetically to the leukemia virus, but different enough to justify a name of its own. Gallo called his newest virus HTLV-1B.

Because most of the differences in the "1B strain" followed the same pattern as those in the feline virus variant, it looked like exactly what Gallo had been predicting in the way of a cell-killing mutant.

In mid-January of 1984, Gallo dispatched a new article to Science reporting the isolation of HTLV-1B from a patient with AIDS. "We were very excited," recalled one of the scientists in Gallo's lab.

The 1B paper had not yet appeared when, in early February, 250 of the world's leading researchers gathered at Park City, Utah, for what would be the biggest scientific conference thus far devoted exclusively to AIDS. As at Cold Spring Harbor, Gallo would be the star. "You are the keynote speaker," Harvard's Jerry Groopman, one of the conference organizers, had written to him earlier. "You can speak for 45 minutes, 90 minutes, or two days if you would like."

According to notes taken by one scientist in the audience, Gallo began his keynote address by declaring that the "only candidate" for an AIDS virus was one of the HTLVs—maybe HTLV-1, possibly HTLV-1B. Whether they were leukemia viruses or AIDS viruses, Gallo said, they were all "one big family."

On the last day of the Park City meeting Gallo dictated a letter to Jay Levy, who had made some comments to a reporter that Gallo considered misinformed. Levy had suggested that the reporter ask Gallo why, if HTLV caused AIDS, there weren't many AIDS patients who also had leukemia. "I never said HTLV caused AIDS," Gallo wrote to Levy. Then he added, "HTLV itself, nonetheless, could still cause AIDS."

Luc Montagnier had had a hard time at Cold Spring Harbor, and David Klatzmann had been virtually ignored in New York City. Perhaps Jean-Claude Chermann, the chief of the Pasteur lab where the French virus had been isolated, would be more successful in Park City.

Chermann had known Gallo for nearly 20 years. The two men had been to each other's homes and dined with each other's families. But when they had last seen one another, in early October, 1983, at a meeting in Seillac, France, there had been an unaccustomed tension between them. "In October we know that we have the virus," Chermann recalled in his heavily accented English. "But everybody was saying that we were wrong."

In the belief that the scientific community was taking its cues from Gallo, Chermann said, he made one last appeal in Seillac to his old friend. "We took a bicycle ride," Chermann said, "and I said to Gallo, you know me for a long time. I can tell you we have the virus. I will not fight anymore with you. The next meeting will be in Park City, Utah. In February we tell you exactly how LAV is the cause of AIDS."

When Chermann's plane landed in Park City four months later, Gallo was at the airport. As Chermann recalled his conversation with Gallo during the ride into town, "He say, 'You know, Jean-Claude, you are invited to this meeting, but you cannot speak about LAV as a retrovirus.' He say, 'You don't know if it's a retrovirus,' and so on.

"I said, Bob, you know that I am working with retrovirus for 20 years. I will give exactly how we think about the virus. It was very difficult for me to speak. Jerry Groopman came and told Gallo, 'You have to let Jean-Claude speak.' "

Besides Groopman, the other Park City organizer was Michael Gottlieb, the UCLA immunologist who had reported the first cases of AIDS, in five homosexual men from Los Angeles, nearly three years before. The previous spring, a few weeks after the Pasteur group had published the BRU paper in Science, Gottlieb had heard Chermann and Klatzmann speak at a sparsely attended meeting in Naples.

It was Gottlieb who had discovered the most important clinical feature of AIDS patients, the depletion of their helper T-cells, and when he heard the news from Paris about a virus that killed those same cells he was electrified. "The words that come to mind are amazed, astonished," Gottlieb said. "I was sitting there hearing something that clicked, saying, these guys have found something important, these guys are on the right track." At breakfast the next morning, Gottlieb invited Chermann to Park City.

Park City is a ski resort in winter, and Gottlieb admits that "at these ski meetings, the pressure is to get the morning meeting done by noon so we can get out onto the slopes." Chermann had been given a place near the end of the morning program. At the last minute, Gottlieb recalled, Groopman and Gallo, who was chairing the session, added a Harvard researcher named William Haseltine to the program ahead of Chermann.

"I had been told by Groopman that Haseltine was only going to talk for 10 minutes," Gottlieb said. "Haseltine is still going at 30 minutes, and it looks like he's going for 45. I went to Groopman and I said, 'Hey, Jerry, this is your guy and he's cutting into Chermann's time.' Jerry got the chair's attention, and Gallo said something to Haseltine. Jerry told me later that Haseltine was livid."

When Chermann finally spoke, Gottlieb recalled, "he was a little flustered by the events, and his English isn't that great anyway. Jean-Claude—I love him—he's a great guy, but his presentation was a little discombobulated. But people were sitting there ready to go skiing and all of a sudden there were people saying, 'Hey, these guys have something.' These were people who hadn't read the Science paper; they hadn't heard the story."

Chermann provided an impressive summary of what the French had accomplished in less than a year: 10 isolates of their virus from patients with AIDS or pre-AIDS, the attraction of the virus for helper T-cells, even a new picture of the virus showing clearly that it didn't look anything like Gallo's leukemia virus. Chermann also presented new data showing that the Pasteur's AIDS blood test had found antibodies to the virus in nearly 40 percent of AIDS patients, and in almost 75 percent of those with pre-AIDS.

Those numbers were a quantum leap from the ones Montagnier had brought to Cold Spring Harbor, and following Chermann's talk a small group of American scientists paid a clandestine visit to his room. They wanted him to know, one of them recalled, that no matter what Gallo thought they had been convinced. As far as they were concerned, the cause of AIDS was the French virus called LAV.

The data from Paris were looking good, but in Gallo's lab there was trouble. Not long after the paper on the discovery of HTLV-1B had been submitted to Science, someone had discovered that the virus hadn't been isolated from an AIDS patient after all. It had come instead from a Zairean man named Elomata, one of the blood samples Jacques Leibowitch had brought Gallo from Paris. Elomata had died of adult T-cell leukemia, not AIDS, which meant that HTLV-1B was just a new variant of Gallo's leukemia virus.

"There was a mixup between the different DNAs," said one scientist who worked on HTLV-1B, explaining that someone in Gallo's lab had mistaken a 7 for a 1. Whatever occurred, overnight Gallo's AIDS virus candidate had vanished into the great, dark void of laboratory error. The paper on HTLV-1B that had been sent to Science never appeared, and it was not the only paper from Gallo's lab to disappear before publication during the long winter of 1984.

In early March, Gallo wrote the editor of the Lancet to ask that the paper submitted the previous December, the one showing that very low percentages of AIDS patients had antibodies to the leukemia virus, also be put on hold. His lab, Gallo said, had recently obtained "over 40 new virus isolates" from patients with AIDS and pre-AIDS, viruses that were "significantly" different from the leukemia virus or any of its known variants.

"My concern," Gallo wrote, "is that the mostly negative HTLV-1 data will be construed as negative to all HTLV. I need some time to think about the best way to present this to avoid confusion."

With the exception of the ill-fated HTLV-1B, Gallo hadn't mentioned anything about a new AIDS virus when he spoke at Park City less than a month before. But when the proceedings of the meeting were published several months later, they contained a paper by Gallo reporting the isolation of a new human retrovirus called HTLV-3 from "a large number" of AIDS patients.

"The week after the meeting," recalled Mike Gottlieb, who as one of the organizers was responsible for collecting and publishing the papers delivered at Park City, "someone in Gallo's lab called and told me they were going to send me a manuscript and to keep it quiet, to keep the information confidential.

"It's not kosher, but I had no sense at the time of what was about to happen. I don't want to look stupid or naive, but I certainly was naive. I did not read it carefully enough to appreciate the significance of the work or the political overtones." There "definitely" should have been a footnote to Gallo's paper pointing out that it was not delivered at the symposium, Gottlieb says, but there wasn't.

When the proceedings of the Cold Spring Harbor conference the previous September were published in the summer of 1984, they also lacked any indication that Gallo's introductory lecture had been rewritten. According to the new version, Gallo had obtained "over 50 isolates of a retrovirus from AIDS or pre-AIDS patients" called HTLV-3, which was "closely related to, but distinguishable from, HTLV-I and HTLV-II." Gallo's other Cold Spring Harbor paper, the one in which he had discussed "the possibility that HTLV plays an important role in the origin of AIDS," had vanished from the proceedings altogether.

If Gallo's discovery of HTLV-3 seemed to settle the cause of AIDS, it left open the question of Max Essex and his antibody test. If HTLV-3 was the cause of AIDS, then it wasn't HTLV-1. If it wasn't HTLV-1, then something was the matter with the Essex test. In March of 1984 the U.S. Patent Office agreed, rejecting the Harvard application for a patent on Essex's test on the ground that it was "inoperative and therefore lacks utility."

In other words, the Essex test didn't work. Or, rather, it worked too well. "I think Max is very lucky, or unlucky," said Cy Cabradilla, who tried to replicate the test for the Centers for Disease Control. "I took that procedure back to CDC, and we did get results that were very comparable." But when blood from people who didn't have AIDS was tested, Cabradilla said, "we were getting the same results."

Whatever the Essex test measured, it wasn't Gallo's leukemia virus. Gallo says now that although he had long suspected Essex's data were wrong, "in time I recognized how wrong. Did I know it then? Perhaps. Are you getting me on a weak point? Probably. I really don't know what he was detecting."

When Essex, who has never retracted his HTLV antibody papers, shared the Lasker prize with Gallo three years ago, the citation noted their "unique contributions to the understanding of AIDS." Last year, when Harvard created a university-wide office to coordinate its research on AIDS, Max Essex was the man it put in charge. Essex declined a request for an interview with The Tribune, citing "a heavy travel commitment and a tight schedule."

4 'Could you patent the sun?'

The afternoon of April 23, 1984, was one of those occasions relished by the federal government, a rare chance for the bureaucrats to go before the television cameras with their white hats on. As the medical writers filed into the cramped auditorium shortly after lunchtime, they were handed an eight-page release from the National Cancer Institute's press office. Soon they were listening to Margaret Heckler, the secretary of health and human services, announcing that "the probable cause of AIDS has been found."

It was, Heckler said, a new virus, and its discoverer was "our eminent Dr. Robert Gallo," chief of the National Cancer Institute's Laboratory of Tumor Cell Biology. Those reporters who wanted the scientific details were handed preprints of four articles by Gallo that would appear 10 days later in Science magazine. "Getting one paper in Science is a lot," Gallo said later. "Getting two is fantastic. Getting three was a record. We had four at one time."

The first article described the new virus, which Gallo had named HTLV-3, as the latest member of the human leukemia virus family on which he had built his scientific reputation. The second article reported the isolation of the virus from nearly 50 patients with AIDS or pre-AIDS, the third described its major proteins, and the last reported the invention of a blood test for antibodies to the virus.

Like many big stories in Washington Gallo's discovery began as a news leak, and before the story had played itself out it would reveal as much about the science of politics as about the politics of science. It broke on Monday, April 16, when the Wall Street Journal reported, "Speculation is mounting in the medical community that researchers soon will announce discovery of a new variation of human cancer virus that may cause acquired immune deficiency syndrome." Gallo's leukemia virus, the Journal noted, "has been suspected of causing AIDS since it was isolated in an AIDS victim last year."

Most scientists agree, and Gallo concurs, that the first word of a major discovery should come not at a news conference but in a scholarly article that has been subjected to prepublication scrutiny by independent experts in the field. "Science is after peer review," he told The Tribune. "You can't just go putting stuff in notebooks and handing them to reporters." The fact that his own landmark discovery was announced at a news conference, Gallo said, "wasn't my idea. It was as the result of a reporter that things hit the fan."

Gallo was referring to Martin Redfern, a science correspondent for the British Broadcasing Corp., whom Gallo has accused of stealing copies of the unpublished Science papers from his office. Redfern emphatically denies the accusation and gives a different version of events. A few days before the news conference, Redfern says, he stopped in Washington to interview Gallo about his leukemia virus research. Halfway through the conversation, Redfern said, Gallo told him that "we've just discovered the cause of AIDS."

"When the interview had finished," Redfern recalled, "he said, 'Would you like preprints of the papers?' To which I said, 'Dead right.' He asked one of his colleagues to get them out. The chap's eyes opened rather wide and he said, 'Are you sure? All four of the AIDS papers?' And Gallo said, 'Yes, I trust this man.' There were several people around who were a little surprised that he'd given me the story."

In a 1987 interview with the Dutch newspaper Financiel Dagblad, Gallo maintained that "after the interview, when I left my room for lunch, he took private documents from my desk."

Redfern says that he promised Gallo he would keep the story to himself unless it broke first somewhere else, and that he reported what he knew only after the leak had appeared in the Wall Street Journal. In fact, it was Gallo himself who first disclosed the existence of HTLV-3 a month before the Journal article appeared, in a speech in mid-March to a meeting of the French Association for Cancer Research in Marseille.

To the millions of Americans who watched the evening news and read the next morning's newspapers, however, Gallo's news conference seemed a genuinely historic moment. Three years ago AIDS hadn't even been recognized. Two years ago it didn't have a name, and now an American cancer researcher had found the cause.

AIDS was fast becoming a partisan issue, and behind all the self-congratulation there were unmistakable political overtones. With increasing frequency the Reagan administration was being accused, not just by homosexual groups but by scientists and some members of Congress, of not having done enough or spent enough, quickly enough, to gain a foothold in the battle against the disease.

But here was Secretary Heckler telling the critics they could thank the Reagan administration for the fact that the cause of AIDS had been found, and with it a test to screen the blood supply for contamination with the virus. A vaccine to protect the uninfected, she said, might be available within two years. Heckler's optimism about an AIDS vaccine was unfounded, and much of what was said that April afternoon would not bear up later under scrutiny.

Near the end of the news conference, a reporter asked Gallo when he had actually made his momentous discovery. When, precisely, had he isolated the AIDS virus? "When you see the papers published in Science," Gallo said, "you will see that we've been mass-producing it for six months. Okay?"

Six months before the news conference was late October of 1983. But the minutes of Gallo's AIDS task force meetings for November and December contain no indication that the AIDS virus had even been identified, much less mass-produced, by Gallo's lab. Instead, the minutes reflect a mounting concern among the task force members about the lack of any solid link between AIDS and Gallo's leukemia virus.

The question of just when Gallo's lab found the AIDS virus is further obscured by his assertion to The Tribune

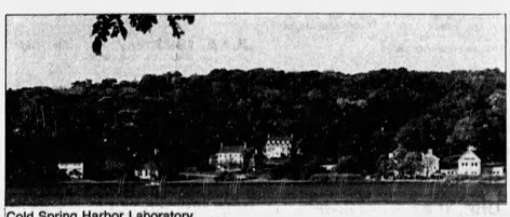
AUG. 4, 1983: Gallo and others conclude that **Charles Robinson** did not have mycosis fungoides but died of "a new form" of lymphoma very similar to ATL.

AUG. 15, 1983: Gallo receives a sample of **BRU's** serum from Paris. Same day, **Essex** sends a paper to Science reporting that hemophiliacs are also positive for antibodies to HTLV.

AUG. 26, 1983: The Pasteur group and collaborating French physicians send Nature magazine a paper reporting that LAV infects and kills helper T-cells, the same kind of cells whose disappearance causes an immune deficiency in AIDS patients. The paper, which provides the strongest link yet between the French virus and AIDS, is rejected.



Cold Spring Harbor Laboratory

SEPT. 14, 1983: A major conference on HTLV begins at Long Island's Cold Spring Harbor laboratory with an introduction by **Gallo**, who says he believes HTLV is involved in AIDS.

SEPT. 15, 1983: **Montagnier**, who is given only 20 minutes to speak, tells the conference his group has found LAV antibodies in nearly three-quarters of patients with pre-AIDS and in 20 percent with AIDS. Same day, Pasteur lawyers apply for a European patent on the LAV blood test used in the studies.

SEPT. 20, 1983: Gallo writes another scientist that he now has 11 isolates of HTLV "and related retroviruses" from AIDS patients.

SEPT. 22, 1983: A second shipment of LAV is delivered to **Gallo's** lab. **Mikulas Popovic, Gallo's** chief virologist, signs a receipt promising that it will not be used for commercial purposes. **Popovic** immediately begins trying to grow the virus and sends a small amount to **Matthew Gonda** in Frederick, Md., for observation under the electron microscope.

SEPT. 27, 1983: Gallo writes a German scientist that a genetic variant of HTLV is the "most likely" candidate for an AIDS virus, adding, "I have never seen the virus that **Luc Montagnier** has described." Same day, **Gallo's** assistants give him a copy of their unpublished paper reporting fewer than 10 percent of AIDS patients have antibodies to HTLV-1.

Continued from preceding page

that "in the month of January we had all essential data," and that by the time of the symposium in Park City in early February "we knew everything that we published."

According to Gallo's lab records, it was in mid-January that he sent to Science the paper reporting the discovery of HTLV-1B in an American homosexual with AIDS. It was during the Park City meeting that Gallo had admonished Jay Levy, the University of California virologist, that "HTLV itself" might be the cause of AIDS.

Gallo's records show, moreover, that some of the essential data contained in the four Science papers could not have existed until less than a month before the papers were submitted for publication at the end of March, and the discrepancies between the data in the records and the published articles suggest the haste with which they were assembled.

Three weeks before the news conference, Gallo flew to Paris to confer with the AIDS team at the Pasteur Institute. As Luc Montagnier remembers the meeting, Gallo told the French that he would soon be announcing his discovery of the cause of AIDS. "He said that he would have several papers published shortly in Science and he didn't know exactly how this would be announced," Montagnier said, "that perhaps a press conference would be done."

The French, who had been trying to persuade the scientific community for nearly a year that the virus they called LAV was the cause of AIDS, were taken aback. The day after Gallo's visit, they had published a paper in the Lancet, their first in a major journal in nearly a year, reporting the latest evidence linking their virus with AIDS.

According to Jean-Claude Chermann, in whose lab LAV had been discovered, Gallo assured the French that he thought his virus and theirs were the same and that he didn't intend to take any of the credit that rightfully belonged to the Pasteur Institute. After the news conference, Gallo telephoned Montagnier in Paris. "He said, 'It's over now,' " Montagnier recalled. " 'I mentioned your contribution and I think everything is fine.' "

Gallo has said repeatedly since then that he acknowledged at the news conference that the two viruses were the same. An official transcript of the news conference, however, does not contain such a statement. When a reporter asked Gallo whether the two viruses were the same, Gallo said, "It may in time be the same as what has been called LAV in a couple of publications," but he added that "I cannot say at this point whether the viruses are identical."

In that morning's Washington Post, Gallo had cautioned that "only time will tell" if the two viruses were the same. He was "astounded," he said, by the "hullabaloo" caused by "sour-grapes" comments from unnamed scientists "who seem to be threatened by my data." When the four Science papers were published 10 days later, one of them contained the assertion that "HTLV-III and LAV may be different."

Predictably, Gallo's comments caused consternation at the Pasteur. "He was just saying, we don't know if it be the same," Chermann said. "And that, scientifically for me, ethically and morally, was not acceptable." Chermann recalls that when he brought the matter up later, Gallo blamed his staff: "He say, 'I put all my people in the room and we discuss. At the end we ask, is the same or is not the same? And people say is not the same.' "

The question Gallo had left hanging—were the two viruses the same?—was not a trivial one for those engaged in the search for a vaccine and a cure. As Richard M. Krause, then-director of the National Institute of Allergies and Infectious Diseases, wrote in a memo to the head of NIH, "It is important to learn if HTLV-3 and LAV are one and the same virus, or are two somewhat different viruses each able to produce a syndrome that resembles AIDS."

According to records from Gallo's lab, experiments by his assistants had already produced evidence that his virus and the one from Paris were the same.

In the months before the news conference, Gallo's staff had begun a series of tests on several cell cultures in which they hoped the new AIDS virus was growing, mixing the cultures with blood serum known to contain antibodies to the AIDS virus. If the antibodies in the serum attached themselves to the cells, it meant the virus was present in the cultures.

Gallo's lab had several sources of serum from which to choose, including some from a hemophiliac with pre-AIDS identified as ET, and some from a laboratory rabbit that had been deliberately injected with the AIDS virus. According to Gallo's published papers, almost every one of the AIDS virus cultures showed a strong positive reaction to both the rabbit and ET.

Although it was not mentioned in any of his articles, Gallo had a third source of AIDS virus antibodies with which to test his cultures. In the summer of 1983, Luc Montagnier had sent Gallo a sample of blood serum from BRU, which experiments at the Pasteur had already shown was loaded with antibodies to the French virus—not surprising, since BRU was the source of the original French isolate.

When Gallo's assistants mixed BRU's serum with the cells where the AIDS virus was believed to be growing, the lab notes show, in some cases the reactions were more intense than with the serum from ET. If BRU had antibodies to Gallo's AIDS virus, then the Gallo virus and the French virus were almost certainly the same. But none of Gallo's Science articles reported that BRU's serum had even been used in the experiments, much less that the reactions had been positive.

As the controversy between Paris and Bethesda over who had been first to discover the AIDS virus began to generate heat, Gallo changed direction. Even if he and the French had isolated the same virus, he began to say, his lab had been first to develop a working blood test for the AIDS virus and first to prove that the virus was the cause of the disease.

According to Nature magazine, when Gallo and Montagnier shared the Lasker Prize in September of 1986 the news release, which had originally credited Montagnier with the discovery of the AIDS virus, was changed at the last minute because of objections from the American jurors to cite him for having found a virus that was "later shown to be the cause of AIDS."

The distinction is far from academic. Finding a new virus in a patient with a new disease, or even in several such patients, is not the same as discovering the cause of the disease. The new virus might be the cause, but so might some other virus still lurking in the background. To link a specific virus with a specific disease, it is necessary to show that everyone who has the disease is infected with the virus, by finding viral antibodies in the blood of large numbers of people who are sick. Before such a search could be mounted, however, there would have to be a blood test for AIDS. (See TEST, p. x.)

In the two centuries since Priestly and Lavoisier raced each other to discover oxygen, the desire to be first has helped push science forward. Nobels and Laskers have stepped up the pace. But there was much more than prizes and prestige riding on the development of a successful AIDS test.

Whether it was French or American, a test for AIDS would be a most welcome development from a public health standpoint. Although it had been clear for at least two years that AIDS was being spread through blood transfusions as well as sexual intercourse, there hadn't been any way to screen the blood supply.

As the number of people with AIDS grew, so did the market for such a test, and most of it was in the United States. Just to keep the domestic blood supply pure, the federal government estimated that 23 million tests would be needed each year, and that didn't take account of the growing demand from people in this country and abroad who wished to find out whether they had been infected.

The Reagan administration was much less interested in patent royalties than in the domestic and international political considerations of being first with an AIDS test. But for a nonprofit institution like the Pasteur that receives less than half its funding from the French government, the royalties from what has become a $175 million-a-year AIDS test market in the U.S. alone would pay for a great deal of research.

To the National Cancer Institute, stepping to the forefront of AIDS research could mean a welcome end to the long dry spell of budget increases that had followed the reverses of the government'a war on cancer. For Gallo and his senior assistants, an AIDS test patent would mean hundreds of thousands of dollars in royalty payments in addition to their government salaries.

By February of 1984 Gallo's lab had developed an AIDS blood test, called an ELISA, that is fundamentally the same as the test employed today by hospitals, clinics and blood banks around the world to guard the blood supply. As soon as it was ready, Gallo asked the Centers for Disease Control to send him a large number of blood samples from patients with AIDS and pre-AIDS with which he could prove its accuracy.

Among the more than 200 blood samples the CDC shipped to Bethesda on Feb. 27 were a number from men and women who didn't have AIDS and didn't belong to any of the groups most likely to get it. All the samples were "blind," labeled only with a code number that gave no indication of whether the donor was sick or well. If Gallo's ELISA could distinguish between them—if the sick donors had antibodies to his virus and the well donors didn't—it would prove not only that his blood test worked but also that his virus was the cause of AIDS.

A few weeks later the CDC gave Gallo the results. His ELISA had done so well that there was no doubt his virus was the cause of AIDS. But when Gallo arrived in Paris in early April to inform the French of the impending announcement of his discovery, he was met with a surprise. In the belief that the French should be given a chance to test their ELISA on the same blood samples, the CDC had shipped a second set to the Pasteur.

Among those at the Paris meeting was Donald Francis, the CDC epidemiologist in charge of ELISA testing. Francis, who has both a medical degree and a Harvard Ph.D. he earned in Max Essex's lab, had brought with an 11-page, single-spaced computer printout that contained the scores for both sides.

"We sat there in Jean-Claude Chermann's office with the printout, three or four fingers going down these columns, looking at the similarities and dissimilarities," Francis recalled. When they reached the bottom, it was clear that the French ELISA had scored as well as Gallo's. Both teams had gotten the right answer on 78 percent of the samples tested, but Gallo had marked many of his blood samples "plus-minus," scientific shorthand for "maybe it's there and maybe it's not."

"Gallo really cranked up the specificity on his test to make sure he wouldn't miss anything," Francis said, adding that Gallo had scored more than twice as many false positives as a result. When all the "plus-minuses" were changed to positives, Gallo scored 81 percent and the French, who had many fewer "plus-minuses," had 79 percent. Despite his slight margin in the corrected scores, two things were now obvious: Both the French virus and Gallo's were the cause of AIDS, and the French had an equally reliable test.

There had been considerable tension during the Paris meeting—at one point Gallo had insisted that Don Francis leave the room because he wasn't a practicing virologist—and that evening Chermann took everybody to the Paradis Latin, a glitzy supper club on the fringes of the Latin Quarter with a topless floorshow. According to Chermann, when he and Gallo found themselves in the men's room, Gallo suggested that perhaps the blood test results should be announced by himself and the Pasteur.

"We can do this together," Chermann recalls Gallo telling him. "We don't need CDC." Chermann was flabbergasted, but no more so than Francis, who remembers Gallo telling him the next morning at breakfast: "You and I can do this together. We don't need the French."

In the end, Gallo did it alone. At the news conference two weeks later he didn't mention that the French virus had passed the same test, and Gallo now hints that he mistrusted the CDC's results from the beginning. "I never stood over that code and went through it with them," Gallo told The Tribune. "How do I know and how do you know? It was in their hands."

The French were eager to publish the results of their performance in the CDC competition. Because the testing had been done in collaboration with Gallo, Montagnier said, the French felt the results should also be published jointly. "Enclosed is a draft of the comparative serology which we discussed last April in Paris," Francis wrote to Gallo in October, 1984. "Please send me comments, authors and corrections as soon as possible."

When Gallo replied two months later, his primary interest seemed to be in the apportionment of credit. "If LAV precedes HTLV-III in this paper as a title then I will be last author," he wrote to Francis. "If not, I don't care who the last author is. (One or the other Don, but not both for your friends abroad). If there is a problem for you then let's just forget the whole thing."

The results of the blood testing were never published. Two years later, when Gallo prepared a sworn statement recounting the history of his AIDS research, he maintained that at the time of the news conference in April of 1984, "my colleagues and I did not consider LAV and HTLV-III to be the same, or even substantially the same, virus. Quite clearly the data available to us indicated that the two viruses functioned differently and reacted differently."

More than 30 years ago, broadcaster Edward R. Murrow asked Jonas Salk who should own the rights to the polio vaccine that bears his name. "Well, the people, I would say," Salk replied. "There is no patent. Could you patent the sun?"

It is still not possible to patent the sun, or any of nature's original constituents. But it is possible to patent a useful rearrangement of nature, and when the Supreme Court ruled in 1980 that the patent and trademark laws could be applied to the products of genetic engineering—in that particular case, to a microbe that ingests petroleum and might be useful in cleaning up oil spills—the biotechnology industry was born.

On Sept. 15, 1983, as Luc Montagnier was announcing the Pasteur's initial ELISA results at Cold Spring Harbor, the institute's attorneys were in London filing an application for a patent on the Pasteur ELISA made with LAV. In early December, while Gallo was still trying to unravel the mysteries of HTLV-1B and the Essex test, the Pasteur filed an application for an American patent.

But as Gallo and Margaret Heckler stood before the television cameras in late April of 1984, the Pasteur no longer had the field to itself. A few hours before the news conference, the U.S. government filed an application of its own for a patent on the ELISA made with Gallo's AIDS virus, HTLV-3. The application included a sworn declaration in which Gallo stated that he was "the original, first and sole inventor" of the AIDS ELISA.

The stakes riding on the competing applications were enormous. If the American patent were granted to Pasteur, it meant no other AIDS test could be produced and sold in this country without paying royalties to the French. If the U.S. government's application prevailed, Pasteur would be shut out of the only market that really mattered.

In patent law priority is everything, and in the case of the AIDS test there didn't seem to be any question about who had finished first. Although Gallo later asserted in scientific articles that the first AIDS blood testing had been done in his lab, the Pasteur had been using its ELISA to test blood samples for months before Gallo even had a virus to test with.

The previous November, while Gallo was still deciding whether to publish the data showing that most AIDS patients weren't infected with his leukemia virus, the French were running the first controlled test of their ELISA with blood samples from the CDC. On the very day the CDC shipped blood samples to Gallo's lab, in fact, the Pasteur team was reporting the results of their ELISA tests in a French medical journal. But when the Gallo AIDS test patent was granted in May of 1985, the Pasteur's application was still gathering dust.

The French, Gallo said later, hadn't received the patent "because they didn't have a working test." In 1985, when the Pasteur Institute filed a formal challenge to the Gallo AIDS test patent, Gallo declared in a sworn statement that while he was "satisfied that HTLV-III had been proven to be the cause of AIDS. . . . I saw no evidence of this for LAV up through the allowance of the Gallo patent."

Such accusations greatly distress the French. "We had the test by the summer of 1983," Montagnier says. "The test was not as sensitive as it is now, so we missed more than half of the AIDS patients. But for people who were just healthy carriers it was OK. We could detect a very high proportion. It could have been used for blood supplies."

Montagnier wrote to the French Ministry of Health offering the ELISA to test the French blood supply and screen potential donors. "I got a nice answer but nothing was done," he said. "People did not believe. Even some of my French colleagues said, well, you have a new retrovirus. But why do you have to involve that retrovirus in AIDS? AIDS is caused by HTLV-1."

"We should have been able to produce the test for commercial use," Montagnier says. "It could have been done. Some time, perhaps a few months, could have been gained, if people had believed what we said. Some lives could have been saved."

When Gallo announced his AIDS virus in April of 1984, it had been more than eight months since the French had first sent a sample of their virus to Gallo's lab. But Gallo told the reporters he hadn't been able to compare his virus to theirs because the French hadn't sent enough to make such comparisons possible. "There could not be a definitive answer from the lack of material that was sent to us," Gallo said. "That's what's been the delay." In a letter to Chermann that summer, Gallo reaffirmed that "the material you sent to us was inadequate for comparative studies."

Gallo maintains that there was no virus in the small vial of frozen liquid that Montagnier had brought to Bethesda in July of 1983. According to Montagnier, when he delivered the vial to Gallo's home Gallo put it in the vegetable crisper of the family refrigerator where it eventually thawed, allowing the virus to die.

Whatever happened to the July shipment, a week after the confrontation between Gallo and Montagnier at Cold Spring Harbor the following September a second shipment of virus was on the way from Paris to Bethesda. Now that the French had applied for a patent on their virus, they asked Gallo to agree in writing that the sample would not be used for any commercial or industrial purpose.

On Sept. 22, 1983, the day the second shipment arrived in Bethesda, Mikulas Popovic, Gallo's chief virologist, began trying to grow it in the same kind of helper T-cells from fresh umbilical cord blood in which the French had first isolated the virus from BRU.

Although Chermann recalls Gallo telling him in Park City that "nobody believes your virus is a retrovirus," Gallo's lab records show that the French virus was kept alive in the cord blood culture for several weeks while Popovic established two critical facts: that the French had discovered a human retrovirus, and that it wasn't Gallo's leukemia virus.

According to the records, Gallo's lab also had visual evidence that the French virus was unique. On the same day the cord blood cultures were set up, Popovic sent a sample of the virus to Gonda's electron microscope lab in Frederick. Within a few days Gonda reported that the electron microscope showed a particle that looked like a lentivirus.

Growing the AIDS virus in fresh white blood cells, as both Popovic and the French had done, is not the only way of keeping it "alive." A more efficient method is to put the virus in a self-propagating culture known as a permanent cell line, but Gallo has repeatedly asserted that his lab was unable to grow the French virus successfully in such a cell line. (See LINE, p. x.)

The virus, he wrote in the first of the four Science articles published in May, 1984, "has not yet been transmitted to a permanently growing cell line for true isolation and therefore has been difficult to obtain in quantity." According to a 1986 memo from Popovic to Gallo, however, in December of 1983 the French AIDS virus was "successfully transmitted" into a permanent cell line, called Ti7.4, which "yielded reproducible but low-level LAV."

In his conversation with The Tribune, Gallo said that the laboratory comparisons between his AIDS virus and the one from Paris had never been made, and that his failure to make them was "the one thing that I regret. It is true

Popovic memo about LAV

Final paragraph from memo dated Aug. 19, 1985, from Mikulas Popovic to Robert Gallo and associate NCI director Peter Fischinger, reporting that the French AIDS virus was grown successfully in Gallo's lab and found to be the same as Gallo's AIDS virus, HTLV-3.

By December 1983 we had prepared specific reagents against HTLV-III. We then transmitted LAV to a cell line developed at M.D. Anderson Hospital known as TI 7.4. This T-cell line yielded reproducible but low-level LAV. We later tested our reagents against this cell line and eventually showed that LAV and HTLV-III had cross-reactive major proteins. We concluded that they could be related viruses or the same general subtype. By January-February 1984 others in our group showed that more than 90% of AIDS sera reacted with HTLV-III specific proteins. We never "scaled-up" LAV for comparable testing but noted that as late as October-November 1983 Montagnier found only 20% AIDS sera reacted with LAV.

Mika Popovic, M.D.

OCT. 3, 1983: **Gonda** tells **Popovic** he has photographed the French virus and it appears to be a lentivirus, a slow-acting retrovirus of a different category than HTLV.

OCT. 6, 1983: **Popovic** determines LAV does not react with antibodies to HTLV, indicating the French have discovered a new human retrovirus.

OCT. 18, 1983: **James Hoxie** sends **Gallo** a blood sample from **RF**, a Haitian immigrant who is dying of AIDS in Philadelphia.

OCT. 19, 1983: A Long Island physician sends **Gallo** malignant tumor cells taken from a 57-year-old carpet salesman infected with the AIDS virus from a blood transfusion.

OCT. 24, 1983: **Gallo's** assistants use LAV to infect five permanent T-cell lines, including HUT78 and Ti7.4.

OCT. 26, 1983: Work is completed on HTLV-1B, a genetic variant of HTLV that Gallo believes may be the cause of AIDS.

NOVEMBER, 1983: The NCI AIDS task force learns that experiments by one of its own members show only 1 of 59 AIDS patients has antibodies to HTLV. The group says "the very low" percentages are "a continuing problem."

NOV. 10, 1983: **Popovic's** notes appear to show that the French virus is reproducing in Ti7.4 and HUT78. The next day, he apparently renames the two cultures HUT78/V and Ti7.4/V.

NOV. 11, 1983: **Gallo** is awarded the American Cancer Society's Medal of Honor.

NOV. 15, 1983: **Popovic** begins the isolation of HTLV-3B by pooling cells from the Long Island carpet salesman and two other patients in HUT78. Same day, he sends **Gonda** samples of the HUT78 and Ti7.4 cultures in which LAV is growing.

NOV. 16, 1983: French immunologist **David Klatzmann** presents the data from the paper rejected by Nature to a meeting of the New York Academy of Sciences. He is virtually ignored.

NOV. 21, 1983: **Popovic's** notes show HUT78/V and Ti7.4/V are "OK," an apparent indication that the French virus continues to grow in both lines.

NOV. 22, 1983: **Popovic's** notes contain the cryptic entry "HUT78/V; Ti7.4/V = MOV." Same day, he adds more material from the initial three patients to his pooled HUT78 culture. In Paris, Pasteur researchers make their first successful infection of a permanent B-cell line with LAV.

NOV. 28, 1983: The University of California's **Jay Levy** says he has isolated the retrovirus he calls ARV from a San Francisco homosexual with AIDS.

NOV. 29, 1983: According to **Popovic's** notes, a new cell line called Htu4, derived from HUT78, is infected with the virus **Popovic** now calls "MOV."

DEC. 5, 1983: Pasteur applies for a U.S. patent on its LAV blood antibody test. **Popovic** sends the virus called MOV to **M.G. Sarngadharan**, the Gallo assistant in charge of developing a blood test for AIDS.

Continued from preceding page

that we had reagents before submitting our papers to have analyzed Montagnier's virus, and to have concluded in those papers that his and ours were essentially the same virus."

The Popovic memos state, however, that the comparisons Gallo mentioned were carried out. The infected Ti7.4 cell line, one memo says, was "used for comparative studies" with the Gallo AIDS virus. "We later tested our reagents against this cell line," the memo maintains, "and eventually showed that LAV and HTLV-III had cross-reactive major proteins." Popovic declined to be interviewed.

Neither Popovic's memos nor the portions of his laboratory notes made public under the Freedom of Information Act contain the data produced by the experiments with the French virus to which the memos refer. According to one memo, however, the initial confirmation that the French virus was growing in the Ti7.4 cell line was obtained on Dec. 14, 1983—the same day Gonda informed Popovic in writing that the virus in that cell line was producing lentivirus particles.

It was also on Dec. 14 that Gallo wrote a letter to a French scientist, not one affiliated with the Pasteur, bringing him up to date on his AIDS virus research. Although his lab had now found antibodies to the human leukemia virus in a number of AIDS patients, Gallo wrote, "We still have not seen the Montagnier group's type of virus in a patient here, nor to my knowledge has anyone else."

The Popovic memos do not appear to contain some of the most important details of his AIDS virus research. According to the memos, the French virus was put into the Ti7.4 cell line in mid-December of 1983—*after* the Gallo AIDS virus had been isolated and used to make the rabbit antibody and the blood test for AIDS. But the lab notes on which the memos are based appear to show that the French virus actually began growing in Ti7.4 on Oct. 24, 1983—three weeks *before* the isolation of the Gallo AIDS virus was begun.

Nor do the Popovic memos mention that Ti7.4 was not the only cell line in which he succeeded in growing the French virus. According to Gallo's lab records, a second T-cell line called HUT78 was also successfully infected with the French virus on Oct. 24.

What ultimately became of the French AIDS virus Popovic was growing in the two cell lines is unclear from his laboratory notes. Popovic later maintained in an interview with Science magazine that the cells in both lines had died after two or three weeks. None of Gallo's lab records that were made public mention the death of either culture, and notes from a different section of Gallo's lab appear to show more than 70 references to further experiments involving LAV in the late winter and spring of 1984.

In January, the notes show, LAV was being compared genetically with the leukemia virus that Gallo incorrectly believed to be the cause of AIDS. In February, DNA was being obtained from "LAV producer human cells." Notes from March and April appear to reflect the use of LAV in several genetic engineering experiments.

Gallo says the handwritten notations are not references to the French virus, but rather a generic designation for the AIDS virus employed by some of his assistants before the name HTLV-3 was adopted in the four Science papers. "We didn't know what to call it," Gallo told The Tribune. "Until we published those papers we had a million and one names."

The lab notes, however, show that the Ti7.4 cell line and other cultures that were clearly infected with the French virus were called LAV, while those infected with other viruses were given different names. The notes also contain several references to LAV that bear dates later than March 30, the day the four papers were submitted to Science.

The fact that Gallo's lab had assembled persuasive evidence months before his news conference that the AIDS virus from Paris was the same as his own was never disclosed to his fellow scientists, to the press or to the public, much less to the researchers at Pasteur.

After the Park City meeting in February of 1984, Chermann was invited to Bethesda to give a talk on LAV. Popovic was in the audience. "Afterward I said to Mika, we send you twice or three times the virus," Chermann recalled. "We need to know if you are replicating or not the virus. And he told me—you know, with his pipe like this—'I cannot speak. Only the boss can speak.' "

5 'Only because there are so many'

In the summer of 1984, the race was over and Robert Gallo had won. With the publication of Gallo's unprecedented four papers in a single issue of Science, the medical community had accepted what the French had been saying for over a year: that AIDS was caused by a new human retrovirus. Now that there was a virus to study, the long march toward a vaccine and a cure could begin.

Still, there were some stray ends that needed tying up. In August, San Francisco's Jay Levy published a paper in Science reporting the isolation of the AIDS virus he called ARV. Levy said he had actually found ARV the previous November, making him the first American to have isolated the AIDS virus. But he was the second American to publish, and that made him an also-ran.

Gallo had a couple loose ends of his own. One was the paper he had withheld from the Lancet in March, reporting that most AIDS patients weren't infected with the human leukemia virus. Another was his paper on HTLV-1B, which had now been rewritten to identify the source of the virus as "an African patient with adult T-cell leukemia." But nobody outside Gallo's lab knew about the mixup with HTLV-1B or that the leukemia virus antibody paper had been held up for many months, and when those papers finally appeared in print hardly anybody noticed.

The only cloud on the horizon that summer was a paper in the Lancet by Robin Weiss and his colleagues in London, who had tested nearly 2,000 Britons for antibodies to the Gallo and French viruses. Half, who weren't at risk for AIDS, had tested negative. Almost all the others, who either had AIDS or were at risk, were positive. Since the CDC competition hadn't ever been published, the Weiss paper represented the first large-scale blood test results for the French virus.

What made the paper even more significant was the way the tests had been conducted. The first virus tested was LAV. But when HTLV-3 was exposed to the LAV-positive samples, all the antibodies had been "sopped up" by the French virus—a clear indication that the two AIDS viruses were the same.

Everyone who had anything to do with AIDS that summer was reading Gallo's papers, and many of them wanted a sample of his new virus to work with. If science was going to find a vaccine or a cure, scientists needed to study the virus that was now officially responsible for having claimed thousands of American lives.

There is a gentlemen's agreement in science that a researcher who claims to have isolated a new virus is obliged to send a sample to anyone who asks. The French, for example, had begun sending their virus to Gallo almost from the day it was discovered. The stated reason for such professional comity is to further the dissemination of scientific information; the unspoken one is to discourage cheating. And while some scientists are quicker than others to honor the unspoken agreement, it is NIH policy that cells, viruses and other materials discovered in its laboratories must be made available "to the field."

Early in April of 1984, workers at the cancer institute's Frederick, Md., facility, which occupies part of the Army's old biological warfare center at Fort Detrick, had begun growing the Gallo virus in enormous quantities. The day before Gallo's papers were published in Science, he wrote to several of his closest colleagues, including Max Essex at Harvard, to say that samples of his new AIDS virus would be available to them within a few weeks—on condition Gallo's name be included as an author on whatever papers they might publish later. But when a letter arrived from Jay Levy asking Gallo for a sample of HTLV-3, it was ignored. "I never got any virus from Bob," Levy says.

"Gallo was being very careful about who he gave the virus to," recalled W. Gerard Robey, who collaborated with Gallo while at Frederick and is now with Abbott Laboratories in Chicago. "He didn't want to give it to everybody and be scooped on half the interesting work."

Among those who had the most problems obtaining the Gallo virus were Donald Francis and his crew at the Centers for Disease Control. Although the CDC and NIH are sister agencies under the umbrella of the federal Public Health Service, there had never been much love lost between the two, and the tension between Francis's lab and Gallo's was especially thick. The CDC's decision to send blood samples to Paris for testing hadn't helped, and neither had the defection to Atlanta of one of Gallo's top assistants, V.S. "Kaly" Kalyanaraman.

"CDC was starting to be a big retrovirology center," recalled Jean-Claude Chermann. "It took Kaly, and some other scientists. Don't forget that the CDC had a lot of money for AIDS. At this time CDC was very important."

What appeared to bother Gallo most was the CDC's collaboration with the French. Don Francis's people had been growing the French virus in Atlanta for some time, and they insisted on referring to the AIDS virus in their papers by its French name, LAV. "I am puzzled," Gallo wrote to a senior CDC official, "by the continual use of LAV. As we have discussed periodically, the generic designation of the virus is HTLV-III/LAV."

According to Berge Hampar, then the general manager of the Frederick facility, while Max Essex and a few other researchers were given "tons of virus for free," the cancer institute charged the CDC $75 a liter. "The CDC actually had to open an account at Frederick," Hampar said. "Isn't that amazing?" Before Gallo would agree to give the CDC his new virus at any price, he made officials there sign a written promise not to compare it genetically with any other AIDS virus they might have growing in their lab.

The year 1983 had been a busy one for Gallo, and 1984 was busier still. When Gallo received the coveted General Motors cancer prize in early June, the citation was read by Robin Weiss, who recalls pointing out that Gallo had "published more papers during the previous year that I had in my entire career."

In between lectures and awards, Gallo continued to press the case for making the AIDS virus the newest member of his leukemia virus family. When the government applied for the patent on Gallo's AIDS test, it asserted that "the biological properties" of the AIDS virus proved that it was "a member of the HTLV family."

In scientific articles and interviews, Gallo elaborated on his rationale for making the AIDS virus the third HTLV. Both the AIDS virus and the other HTLVs were retroviruses, Gallo said, and both preferred to infect helper T-cells. Both viruses had core proteins that were the same size, he said, and their reverse transcriptases, the enzymes they used to reproduce themselves, had the same molecular weight. Both viruses, Gallo said, had a shared sequence of amino acids in the proteins that formed the outer envelopes that protected them when they were outside the cell.

Another of Gallo's arguments was that the leukemia virus and the AIDS virus had probably originated in Africa, and considering the number of AIDS cases there it seemed reasonable that AIDS had its beginnings somewhere on that continent. There wasn't very much adult T-cell leukemia in Africa, however—almost all the known cases had been found in the fishing villages of southwestern Japan—and there was virtually no AIDS in Japan.

Gallo set out to construct an epidemiological bridge between those two very different and distant societies, suggesting that the 16th Century Portuguese explorers who stopped in Japan might have brought with them African slaves or monkeys infected with a virus that eventually evolved into HTLV-1. In a letter to the British journal Nature, Gallo even maintained that the Japanese word for monkey, *amakawa*, was "derived from the Portuguese word macaco also meaning monkey."

When Yorio Hinuma, the Kyoto University virologist who with Isao Miyoshi had established the link between HTLV-1 and T-cell leukemia, heard about Gallo's hypothesis, he wrote his own letter to Nature. Hinuma cited evidence "that HTLV-1 was already present in aboriginal Japanese in pre-historic times." The Japanese word for monkey, Hinuma noted, was not *amakawa,* but *saru.*

The Pasteur's AIDS research group had known from the moment it discovered LAV that it bore no more than a superficial relationship to HTLV-1, and they had demonstrated many of the dissimilarities in their research. But Gallo kept insisting they were wrong.

"The virus, you explained to us, was not related to HTLV," he wrote to Jean-Claude Chermann in July. "We now know that it is related to HTLV-I and clearly belongs to that virus family." In an interview with the BBC a few weeks earlier Gallo went even farther, asserting that his lab had found genetic similarities between the AIDS virus and "the whole genome" of the leukemia virus.

In August of 1984, Gallo published a paper in Science that appeared to contain the first hard evidence to back up his assertions about the similarities between the AIDS virus and HTLV-1. Using a technique called hybridization analysis, which measures the degree to which two strands of DNA will adhere to each other biochemically and are thus alike, sections of the leukemia virus DNA had been found to have the same genetic composition as the AIDS virus DNA.

"The present data," the paper concluded, "support our proposal that this virus should be classified within the HTLV family." In November, Gallo published another paper endorsing the conclusions in his August paper. In a third paper published in December, he termed the genetic similarities between the AIDS and leukemia viruses "significant."

The day before the third paper appeared, dozens of biologists from around the world gathered in Wilson Hall on the tree-lined campus of the National Institutes of Health. They

Breeding ground for killer AIDS virus: Cancer in a jar

Human beings are really not much more than a collection of different kinds of cells: skin cells, blood cells, heart muscle cells, hair-forming cells and thousands of others, each providing some aspect of the body's structure and function. As the body grows or ages or repairs damage to itself, new tissue is formed by the division of existing cells.

The process of cell division can also be induced in the laboratory, by placing cells in a culture that contains the biochemicals and nutrients they need to live and grow. No normal cell will go on multiplying endlessly outside the human body. A skin cell may produce perhaps 50 generations before it dies, other kinds as few as a dozen. The exception is the cancer cell. Cancer, by definition, is the uncontrolled multiplication of a cell, and under the right laboratory conditions human cancer cells will continue to reproduce forever.

The type of cell the AIDS virus prefers to infect is a white blood cell called the helper T-cell, a key component of the human immune system whose role is to direct companion immune system cells, called B-cells, in the production of antibodies designed to kill viruses, bacteria or other invaders. Because the AIDS virus ultimately kills the T-cells it infects, when all the infected T-cells are dead the virus will also stop reproducing. To keep the AIDS virus replicating in the laboratory, it must either be fed a continuous supply of fresh T-cells or placed in culture with a collection of cancerous T-cells that are continuously reproducing on their own, the laboratory equivalent of cancer in a jar.

When a leukemic T-cell line is exposed to particles of the AIDS virus, the particles attach themselves to a particular protein, known as CD4, on the surface of the cells. Using the CD4 protein as a kind of portal, the AIDS virus deposits its genetic material—a single strand of RNA—in the interior of the cell. Once inside, the enzyme called reverse transcriptase begins making virtual carbon copies of the viral RNA in the form of its genetic cousin, DNA. This "proviral" DNA then inserts itself into the much longer strand of DNA that occupies the center of every human cell and contains the individual's complete genetic code.

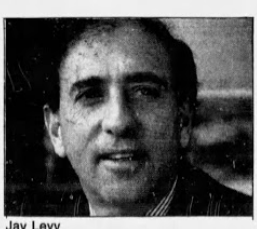
When, through a series of complicated internal and external events, the viral DNA is activated inside the T-cell, it produces new virus particles that burst forth from the occupied cell in search of new T-cells to infect. At the same time, the virus-infected T-cells often begin to divide and multiply. Because each new cell retains a copy of the virus's DNA and thus the ability to produce new particles of virus, the amount of virus in a patient's system—or in an infected T-cell line in a laboratory—can increase very rapidly.

Sooner or later, most AIDS-infected T-cells will be killed by the replicating virus, which does irreversible damage to the cell. However, some leukemic T-cell lines are resistant to the cell-killing effects of the virus. A few lines even seem to be immune, their infected cells apparently capable of surviving and dividing forever while providing a limitless source of virus for scientists to study.

DEC. 12, 1983: **Gallo** sends a paper to Science reporting that the Essex test is probably measuring antibodies to a protein from HTLV itself rather than a hybrid produced by an infected cell.

DEC. 13, 1983: A rabbit injected by **Samgadharan** with the AIDS virus begins producing antibodies that can be used to verify the presence of the virus in human cells.

DEC. 14, 1983: **Gonda** reports observing the AIDS virus in the HUT78 and Ti7.4 cultures in which LAV is growing. **Popovic** confirms LAV is growing in the Ti7.4 cell line. Same day, **Gallo** tells a French scientist, "We still have not seen the Montagnier group's virus in a patient here, nor to my knowledge has anyone else."



Jay Levy

DEC. 16, 1983: **Gallo** sends the Lancet his manuscript reporting fewer than 10 percent of AIDS patients have antibodies to HTLV.

DEC. 20, 1983: At its December meeting, the AIDS task force agrees that whether the Essex test is measuring antibodies to a viral or a cellular protein is now "a major question."

JAN. 2, 1984: **Popovic** sends more MOV to **Samgadharan.** Same day, he adds material from seven new patients to his pooled virus culture, now called "HTJV pool." His notes contain two other entries: "Sarang serolog. O.K.!!!" and

JAN. 6, 1984: The first AIDS virus antibody tests are performed in Gallo's lab on blood samples from patients with AIDS and pre-AIDS.

JAN. 10, 1984: **RF's** cells test negative for reverse transcriptase. **Gallo** tells a colleague that HTLV remains a leading candidate for the cause of AIDS.

JAN. 13, 1984: **Gallo** writes a German researcher that "we now have 18 isolates" of HTLV from AIDS patients, and that "it has become somewhat more likely that HTLV may be involved" in AIDS. He adds that the Essex test, which he had "worried" might be picking up antibody to a cellular protein, is measuring antibody

JAN. 18, 1984: **Gonda** reports that cells from **RF** and patients identified as **LS** and **BK** are all negative for virus. Same day, **Gallo** sends Science a paper reporting the isolation of HTLV-1B from a homosexual with AIDS.

JAN. 19, 1984: According to Gallo laboratory notes, the first experiments are begun in which "LAV" is genetically compared with HTLV-1 and HTLV-2.

JAN. 25, 1984: **Popovic** subdivides the HUT78 cell line, which he now calls HT, into 41

Continued from preceding page

were there partly for the reasons that scientists have always gone to scientific meetings—to see old friends, exchange gossip in the corridors and listen to one another talk—and partly because this meeting offered a special attraction.

In biology the topic of the moment was AIDS, and the group that had assembled that morning in Bethesda could fairly be considered the illuminati of AIDS research. Max Essex and William Haseltine had come down from Harvard. Hilary Koprowski from the Wistar Institute in Philadelphia was there, and so was the grand old man of retrovirology, Ludwik Gross. Once again, however, the star was Gallo, whose discovery of HTLV-3 had brought him almost instant recognition as this country's foremost AIDS researcher.

It was a critical time for AIDS research, as scientists in the U.S. and abroad began to gain their first detailed understanding of the mechanics of the virus that was now killing hemophiliacs, transfusion patients and intravenous drug users as well as homosexuals. Gallo had been chosen to deliver the symposium's opening lecture, and he used the occasion to repeat the many similarities between the AIDS virus and his leukemia virus. So far, the two viruses had been compared only by indirect methods. The only sure way to determine how related they really were was to unravel their DNAs and compare them side by side.

The genetic sequence of the leukemia virus had been worked out by scientists in Japan the year before, and an intensive effort to sequence the Gallo AIDS virus had been underway for months, by researchers in the labs of Gallo, Haseltine and two private companies. "There were 19 of us involved," recalled Lee Ratner, who coordinated the effort from Gallo's lab, "and we worked our tails off for three to four months."

On the other side of the Atlantic, the Pasteur Institute had put together a team of five young scientists to break the genetic code of LAV. Unlike Gallo, they had no stake in whether the AIDS virus was a member of the HTLV family or not, and they had been saying for months that it wasn't. The real value of the AIDS virus sequence was that, once in hand, it would lay open the secrets of how the virus worked—and, perhaps, how it could be made not to work. The Pasteur group had found the virus a year before Gallo, but they were only slightly ahead in the race to decode its DNA.

Before the virus could be sequenced, its DNA had to be cloned—extracted from an infected T-cell and then copied millions of times by inserting it into a bacterium, called E. coli, that is the biological equivalent of a photocopying machine. The reason for the delay in Paris had been the difficulty encountered by the Pasteur's AIDS group in finding someone who wanted to do the cloning.

Ordinarily, the molecular biologists would have leapt to take part in a historic scientific event. But it wasn't yet clear that the project would be historic, and none of them wanted to risk spending months cloning a virus that might not be the cause of AIDS. "At this time nobody was believing us," Chermann recalled. "Pasteur was not believing us, and we were fighting against the Americans."

Chermann's lab was near the institute's computer center, a place where the molecular biologists tended to congregate, and to get there they had to cross his corridor. "I tried to stop some people to say, could you help us to clone," Chermann recalled. "If one had taken the bet, the virus would have been cloned and sequenced before the announcement of HTLV-3."

In the end he and Montagnier persuaded Simon Wain-Hobson, an Oxford-educated British expatriate who was working on the virus that causes hepatitis-B and teaching gene-cloning courses on the side. "Montagnier had asked a number of people on the staff if they wanted to do it, and many people said no," Wain-Hobson recalled. "He and I discussed it for a long time and perhaps we should have got going earlier, but I must confess that I was terribly unimpressed at the time. I said, 'Well I've got a few things to finish off and I'll start as soon as I can.' If he'd made a more convincing case I'd probably have started a bit earlier."

Montagnier also recruited two graduate students from the department of molecular biology, Marc Alizon and Pierre Sonigo. Once the cloning was done, the genetic sequence followed in relatively short order. "It was all over by early November," Wain-Hobson recalled. "We worked in shifts. It took us longer to write the paper than it took to do the sequence, because we're terrible at writing. We tried to make a nice paper of it."

By chance, Montagnier had been invited to speak at the NIH symposium in December, 1984, and as soon as the French sequence was finished he telephoned the symposium's organizer, Samuel Broder, to ask that Wain-Hobson also be allowed to speak. The French, Montagnier told Broder, had data "of great importance" to present, but he didn't say exactly what it was.

When Broder, who has since become the cancer institute's director, agreed, Wain-Hobson and Montagnier began to have second thoughts about showing their genetic sequence on Gallo's turf. If they didn't bring their sequence and Gallo presented his, Wain-Hobson remembers thinking, it would look as though the French were behind. But relations between Gallo and the French had deteriorated so much, Wain-Hobson said, that he wasn't sure what might happen to his data. In the end they decided not to show the sequence itself, but to present instead a "map" of the virus's principal genes, those regions of its DNA that contained the instructions for manufacturing its principal proteins.

Gallo's opening paper was followed by one from Max Essex and another from Gallo's chief molecular biologist, Flossie Wong-Staal. Wain-Hobson had been given only 10 minutes to speak, and when his turn came he didn't waste words. He began by questioning Gallo's published data showing similarities between the AIDS virus and the leukemia virus, and ended by unveiling his genetic map.

Several of those who were present remember the auditorium falling quiet as Wain-Hobson's slide flashed on the screen. According to the French gene map, the AIDS virus and Gallo's leukemia virus were hardly alike. The leukemia virus had only four genes; the AIDS virus had at least five, and there were important differences in their size and placement that made the AIDS virus the most complex human retrovirus yet seen.

The first two genes in the AIDS virus—"gag," which contains the genetic code for its core proteins, and "pol," for the reverse transcriptase—were about the same size and in the same place as in the leukemia virus. But the ends of gag and pol overlapped, and the French AIDS virus had a short third gene called "Q" that the leukemia virus was missing.

Farther down the sequence the real differences began to emerge. The fourth gene in the AIDS virus was "env," the gene that contained the code for the proteins that formed its outer envelope. The leukemia virus had an envelope gene too, but it was only about half as long. And the leukemia virus didn't have anything resembling the fifth gene, "F," that the French had found behind the AIDS virus's envelope.

As soon as Wain-Hobson finished speaking, several members of the Gallo sequencing group left the auditorium. The exodus was led by Haseltine, Gallo's longtime associate from Harvard and a key member of the team that, less than a week before, had finished sequencing the Gallo AIDS virus.

"I remember Bill stomping out of there with a contingent of people," said the CDC's Cy Cabradilla, who was in the audience that day. "I also remember him grabbing people and saying, 'No, no, his sequence is wrong. We've got the right sequence.' Bill Haseltine was very upset. Molecular biologist, cloner, sequencer, supposed to be a top gun, and here he got upstaged by the French."

When it was time for questions the Gallo group filed back to their seats. There were one or two half-hearted queries for some of the other speakers but no questions for Wain-Hobson. One member of the audience remembers thinking that everyone was waiting for Gallo to fire the first shot. If they were, he didn't disappoint them.

"Gallo walked to the microphone," recalled one scientist who was there, "and he said, 'I have a question for Dr. Wain-Hobson.' But he didn't ask a question, he made a speech. He talked for more than 10 minutes."

When Gallo finished, Wain-Hobson recalled, it was with a question. "Why," Gallo wanted to know, "do you stress the differences between HTLV-1 and HTLV-3?"

"Only because there are so many," Wain-Hobson replied.

Gallo now says he cannot recall attending the symposium. "I don't think anybody in our lab went to it," he said. "Who went? I was there?" But Gallo was there, and in the space of 10 minutes he had seen his arguments for the similarities between the AIDS virus and his leukemia virus demolished by his rivals from Paris.

"The people from Gallo's camp couldn't believe it," said Cabradilla, who was working on the sequence of another AIDS virus clone. "They were shocked. This small band of molecular biologists out of the Pasteur Institute had just beaten these guys from NCI and Harvard. Other groups, myself included, were saying, hey, good job."

No one outside the Gallo group will ever know for sure what the Gallo gene map of the AIDS virus looked like that day, because neither Gallo nor his associates presented any of their data at the symposium. But one member of another group that was working feverishly to finish the sequence of Jay Levy's AIDS virus recalls talking to a member of Gallo's staff after the meeting broke up. "I got the distinct impression that Simon Wain-Hobson had the story," the scientist said, "and that everyone else, including us, was close but behind."

Constructing a gene map from a DNA sequence can be compared to translating poetry from a foreign language. The poet's thrust may be obvious, but the elegance of the finished translation will turn on words that can be interpreted in more than one way. For a multitude of reasons, it is possible for two scientists to look at the same DNA sequence and disagree about where a gene begins and ends, or even whether it exists at all.

According to several members of the Gallo group, one of their disagreements with the French was over whether the fifth gene shown in Wain-Hobson's map was a real gene or a mirage. Because the leukemia virus didn't have five genes, the prevailing opinion in Gallo's camp was that the AIDS virus probably didn't either, and that what looked like a fifth gene was simply an error in translation. "Nobody was believing that it was a functional gene," said Nancy Chang, one of the Gallo sequencers. "We thought maybe it was a sequencing error, or not really anything significant."

In late January of 1985, spread across several pages, Nature published the Gallo lab's genetic sequence of the AIDS virus, row after row of a's, c's, g's and t's, more than 9,200 in all. Gallo called the sequence "a significant step forward in understanding how the virus works." AIDS researchers, Haseltine said, could now "see the face of the enemy." But the face drawn by Gallo and Haseltine was that of the wrong enemy. Unlike the French, they were still fighting the last war.

The Gallo sequence paper also contained a gene map, and its first two genes, pol and gag, looked exactly like those in the gene map Simon Wain-Hobson had brought to Bethesda. The Gallo map had a third gene, called "sor," that matched the gene the French called Q. It also contained a fifth gene, "3'orf," but the Gallo group hedged the question of whether the fifth gene really existed or was just an error in translation.

The major difference between Gallo's map and the one drawn by the French was in the fourth gene. If the leukemia virus was any guide, the fourth gene was probably the env, or envelope gene. But it was so much longer than the env gene in the leukemia virus that the Gallo group thought it had to contain the code for some other protein as well. But what function would such a protein be likely to perform?

The leukemia virus had a transactivator gene that appeared to switch the virus on after years, or even decades, of latency. Because the AIDS virus can also remain latent for long periods, the Gallo group thought the second half of the envelope gene was probably the AIDS virus transactivator. Because they weren't sure what it did, they called it "lor," for "long open reading frame." All together, Gallo's fourth gene was "env-lor."

According to Simon Wain-Hobson, Nature had originally expressed interest in publishing the French sequence paper, and when it was finished he gave them a call. "I said, you'll have our paper tomorrow," he said. "And then they didn't want it." Fortunately for the French, a journal called Cell, published by the Massachusetts Institute of Technology, was more receptive.

"They were naturally somewhat upset about this," recalled Benjamin Lewin, the editor of Cell. "They felt they had been working pretty much evenly with Gallo's group and suddenly they were not going to get their paper published maybe until months afterwards. We said, yes, we thought the sequence of the first isolate of the AIDS virus was a significant event. It didn't take us very long to decide that we should publish the paper and that we should publish it

As the cooks squabbled, the alphabet soup boiled down to HIV

As with mountains and galaxies, the naming of new viruses is a scientific honor reserved for their discoverers. Nomenclature in virology dates back to the time, not so long ago, when scientists' names were attached to the viruses they discovered. That is no longer common, but for Robert Gallo the best name for the virus that causes AIDS was the one that ensured its place as the newest member of his family of human retroviruses.

"Any impartial scientist," Gallo wrote to his French counterpart, Luc Montagnier, "will adopt the name HTLV-III. In fact, almost everyone in the U.S. and most people in Europe have already done so."

The French, understandably, preferred the name they had given their own isolate: LAV, which was short for lymphadenopathy-associated virus. Many other researchers, wishing not to anger Gallo but hoping to accord the French due credit as the discoverers, resorted to calling the virus HTLV-3/LAV. But each isolate of the AIDS virus was also given its own designation, and as more viruses were isolated the confusion engendered by such compound names was vastly increased.

The question was further complicated by the fact that the University of California's Jay Levy had found the AIDS virus independently—Levy said he had actually isolated the virus ahead of Gallo, but Gallo had published first—and Levy was calling his virus ARV, for AIDS-related virus.

"LAV is clearly an inaccurate name, and AIDS virus or AIDS related virus is the dumbest name I have heard yet," Gallo wrote to one colleague. "Clearly, human T-lymphotropic virus III is as accurate, as innocuous, and as consistent with the past as any name possible."

When Gallo was pressed for the rationale behind the name HTLV-3, he referred to a meeting at Cold Spring Harbor Laboratory on Long Island in September of 1983, where he had persuaded eight other scientists at a lobster dinner on the beach to join him in signing an "international agreement" that the next new virus related to his original human leukemia virus should be called HTLV-3.

The agreement, said British virologist Robin Weiss, who was among the signatories, had nothing to do with AIDS. It was was intended, he said, to resolve the dispute between Gallo and the Japanese over whether the leukemia virus should be called HTLV-1 or ATLV, the name being used in Japan.

Montagnier was there but wasn't asked to sign, Gallo said later, because "he only had one paper in the literature." In fact, Montagnier wouldn't have signed. "We never used the initials of HTLV," Montagnier wrote to Gallo later. "The initials of HTLV have been coined by you. In renaming this virus HTLV you have induced a lot of confusion amongst unaware people."

Gallo said his choice of names had been mandated by the "Cold Spring Harbor agreement." But in March of 1984 he wrote a personal letter to the editor of a London medical journal saying he was "debating whether to call [the AIDS virus] HTLV-III or HTLV-A (A = AIDS)."

Gallo chastised the French for having taken issue with his choice, imploring Montagnier to "save our energy in trying to contain the virus and the disease rather than to beat a dead horse over nomenclature." But it was Gallo who was firing off angry letters to colleagues whenever the name LAV appeared in a scientific paper. To one longtime collaborator who had used the French designation, Gallo wrote, "I cannot accept the excuse that: [a] 'you did not know,' or [b] 'the journal changed the name.'"

After nearly a year of dispute, the International Committee on the Taxonomy of Viruses stepped in. Under the chairmanship of Harold Varmus, the University of California virologist who won a Nobel prize last month, the committee assembled a panel to choose a new name. The panel included nearly everybody—Gallo and his friends, Robin Weiss, the French and the California ARV researchers—and the consensus was that none of the existing names was really right.

LAV wouldn't do, because it was possible to get AIDS without ever having had lymphadenopathy. ARV wouldn't do, because not everyone who was infected with the virus got AIDS. HTLV-3 was clearly wrong, because the AIDS virus had so little in common with the other HTLVs. The best name the group could come up with was human immunodeficiency virus, or HIV, a choice that Varmus concedes was less than inspired.

But when the 13-member panel published its decision in a letter to Nature, the letter bore only 11 signatures. Gallo and his closest colleague among the panelists, Max Essex of Harvard, had refused to sign.

Gallo vowed later never to use the new name. "The names of the virus that are already in the literature will be maintained," he said at the time. Although his AIDS papers referred to HTLV-3 for more than a year afterward, he has since joined the rest of the scientific community in adopting HIV.

JAN. 30, 1984: Using blood samples sent to Paris by the CDC, the Pasteur group finds antibodies to LAV in 10 of 10 patients with pre-AIDS and 3 of 10 with AIDS.

FEB. 7, 1984: In the keynote address at an AIDS symposium in Park City, Utah, **Gallo** says his "only candidate" for the AIDS virus is a close genetic variant of HTLV-1. His assistants passed a paper reporting that Claude Chandon

FEB. 9, 1984: **Gallo** writes **Jay Levy** that "HTLV itself . . . could still cause AIDS."

FEB. 13, 1984: **RF, SN, LS** and **BK** are still negative for electron microscopy. **Popovic** sends viruses called HTLVA and MO Variant to **Gonda** for observation.

FEB. 23, 1984: Lab notes show DNA being extracted from "LAV producer human cells." The French tell CDC they now have 11 retrovirus isolates from patients with AIDS and pre-AIDS.

FEB. 25, 1984: H9 and several other clones of the HT cell line are infected with the pooled virus culture **Popovic** now calls HT(pool

was infected with HTLV-1. **Jean-Claude Chermann** reveals that antibodies to LAV have now been found in 75 percent of pre-AIDS patients and 38 percent of those with AIDS.

FEB. 8, 1984: Pasteur researchers infect a new permanent cell line called FR8 cell line with LAV.

Robert Gallo (left) and Luc Montagnier

FEB. 14, 1984: Chermann, attending an NCI seminar, asks Popovic if he has succeeded in growing the LAV sent from Paris. "I cannot speak," **Popovic** replies. "Only the boss can speak."

FEB. 22, 1984: Gonda reports observing lentivirus in "HTLVA" and "MO Variant."

FEB. 27, 1984: CDC sends blood samples to **Gallo** and the French for testing with their respective AIDS tests. Same day, Pasteur researchers infect a new cell line called BJAB with LAV.

Biography: *Dr. Ruscetti obtained his Ph.D. from the University of Pittsburgh working on prokaryotic RNA metabolism under Lew Jacobsen, and did postdoctoral work on hematopoiesis under Dane Boggs. From 1975 to 1983, he studied human retroviruses and T cell biology in the National Cancer Institute's Laboratory of Tumor Cell Biology.*

Research: Cell cycle control of cell growth and differentiation is tightly regulated by a series of complex interactions. It is the main tenet of our studies that unrestricted growth control and inappropriate transcriptional activation due to defects in negative regulatory control play a major role in oncogenesis and retroviral pathogenesis.

Transforming Growth Factor β: Growth Inhibition of Stem Cells
In studying negative regulation of hematopoietic stem cell (HSC) growth, we have found TGFβ selectively inhibits the growth of all primitive stem cell populations isolated. Both in vivo and in vitro experiments have shown that HSC's are reversibly prevented from entering the cell cycle after TGFβ treatment regardless of the growth stimulant used. In single cell assays, using highly purified murine HSC, growth inhibition by TGFβ1 was direct. Future projects include disruption of TGFβ growth regulation in stem cell lines and fresh stem cells to test for oncogenic potential and clone genes involved in TGFβ regulation of HSC growth.

Negative Regulation of Viral and Cellular Genes During Retroviral Infection
We previously demonstrated HIV–1 latency in monocytes in vivo. The presence of latently infected monocytes constitutes a possible source for reactivation of virus production during the normal immune response. We have identified immune activation of latently infected monocytes to be a mechanism by which latent HIV–1 can be reactivated to produce infectious virus. Ongoing studies involve identification of these genes as well as signal transduction pathways involved in immune activation of latent HIV–1.

Methylation of the viral LTR is a second mechanism by which HIV–1 and HTLV–I proviral expression is silenced. We have recently demonstrated that these viruses upregulate expression of DNA methyltransferase (metase) in infected cell lines and primary cells. Further, we have identified the IFN-γ gene as a target of this increased DNA metase activity. Thus, increasing DNA metase expression may be another mechanism by which HIV–1 evades the immune response. As aberrant methylation has long been thought to be important in oncogenesis, this may also be a mechanism of tumor development associated with human retroviral infections. Future studies will determine the molecular basis of human retroviral upregulation of DNA metase, if increased methylation of the IFN-γ gene routinely occurs in AIDS patients, and will identify other targets of the increased metase activity.

Although largely unknown, the cellular events triggered by HTLV–I infection in the lymphoproliferative process are of major importance to the establishment of leukemia. We have recently characterized an infectious clone of HTLV–I as well as a susceptible expressing cell line to study the molecular interactions of this infectious clone. We have shown this infectious

Negative Regulation in Viral Pathogenesis

Research: Cell cycle control of cell growth and differentiation is tightly regulated by a series of complex interactions. It is the main tenet of our studies that unrestricted growth control and inappropriate transcriptional activation due to defects in negative regulatory control play a major role in oncogenesis and retroviral pathogenesis.

Transforming Growth Factor ~: Growth Inhibition of Stem Cells

In studying negative regulation of hematopoietic stem cell (HSC) growth, we have found TGF~ selectively inhibits the growth of all primitive stem cell populations isolated. Both in vivo and in vitro experiments have shown that HSC's are reversibly prevented from entering the cell cycle after TGF~treatment regardless of the growth stimulant used. In single cell assays, using highly purified murine HSC, growth inhibition by TGF~I was direct.

Future projects include disruption of TGF~ growth regulation in stem cell lines and fresh stem cells to test for oncogenic potential and clone genes involved in TGF~ regulation of HSC growth.

Negative Regulation of Viral and Cellular Genes During Retroviral Infection

We previously demonstrated HIV-1 latency in monocytes in vivo. The presence of latently infected monocytes constitutes a possible source for reactivation of virus production during the normal immune response. We have identified immune activation of latently infected monocytes to be a mechanism by which latent HIV-1 can be reactivated to produce infectious virus. Ongoing sh1dies involve identification of these genes as well as signal transduction pathways involved in immune activation of latent HIV-1.

Methylation of the viral LTR is a second mechanism by which HIV-1 and HTLV-I proviral expression is silenced. We have recently demonstrated that these viruses upregulate expression of DNA methyltransferase (metase) in infected cell lines and primary cells. Further, we have identified the IFN-y gene as a target of this increased DNA metase activity. Thus, increasing DNA metase expression may be another mechanism by which HIV-1 evades the immune response. As aberrant methylation has long been thought to be important in oncogenesis, this may also be a mechanism of tumor development associated with human retroviral infections. Future studies will determine the molecular basis of human retroviral upregulation of DNA metase, if increased methylation of the IFN-y gene routinely occurs in AIDS patients, and will identify other targets of the increased metase activity.

Although largely unknown, the cellular events triggered by HTLV-I infection in the lymphoproliferative process are of major importance to the establishment of leukemia. We have recently characterized an infectious clone of HTLV-I as well as a susceptible expressing cell line to study the molecular interactions of this infectious clone. We have shown this infectious clone to be highly transforming for T cells. Future studies include delineating viral elements necessary for cytokine-dependent and -independent transformation as well as the signaling pathways, initiated by HTLV-1, resulting in T cell immortalization.

Nobel elicits ignoble ambition

Claim to have discovered HIV undid researcher Robert Gallo

Science Fictions
The War Between the Scientists Who Discovered HIV
By John Crewdson
Little Brown and Co., 688 pages, $39.95

MARK WAINBERG
Special to The Gazette

Studies have shown that peer approval and recognition are the most important factors that motivate scientists to achieve greatness. Many non-scientists might have difficulty identifying with this notion. After all, in the world of business and sports it is seemingly ever-higher salaries and other monetary considerations that drive people to do their best. But for scientists, ultimate recognition is really the Nobel Prize, sought by many and received by few. Among those who either covet a Nobel or who believe that they have a realistic chance of winning one, the quest can become all-consuming.

In this book, John Crewdson, a Pulitzer Prize-winning journalist at the Chicago Tribune, has chronicled the manner in which the need to be identified as the discoverer of HIV, the virus that causes AIDS, caused the well-known virologist Robert Gallo to embark on a course that would prove destructive for Gallo himself as well as for many of his colleagues, including a rival group of scientists at the Pasteur Institute in Paris, headed by professor Luc Montagnier.

The book is a detailed expansion of a riveting series of articles that Crewdson wrote on this subject for the Chicago Tribune in 1996. It includes a wealth of details that were omitted from the original, shorter version, and this is both its strength and its weakness. Notably, while the case that Crewdson, writing almost as a prosecutor, builds against Gallo is compelling, it is so detailed as to risk boring the casual reader.

It is hard to know what might have motivated Crewdson to write this lengthy description of the events surrounding the discovery of HIV. It is clear, however, that he must have felt a need to portray the excesses of human behaviour that can emerge when participants feel that a Nobel Prize is on the line, and that Gallo's excesses in pursuit of this goal were so egregious as to warrant full documentation.

Indeed, the author comes across as an excellent prosecutor. Readers who are fans of courtroom dramas or novels will know that such individuals are determined to obtain a conviction, even if it sometimes means providing an interpretation of events that best fits the prosecutorial thesis. This is clearly the case here thought it is doubtless within the scope of journalistic license.

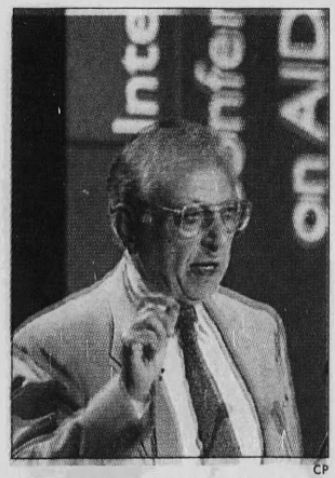
FACTUAL ERRORS

There are, however, several factual errors in this version of events. First, in the introductory pages, Crewdson makes the point that Gallo was extremely stingy and did not make his reagents and resources available to other laboratories for their own research. This is largely untrue. Indeed, the reviewer of this book received HIV from Gallo's lab in 1984, shortly after publication of Gallo's papers in Science (notwithstanding the fact that Gallo had appropriated the virus from the French) as well as cells in which to replicate the virus and monoclonal antibodies with which to perform biochemical analysis.

Gallo also made these reagents available to scientists from many laboratories around the world. Sadly, however, he refused to provide these same materials to many others, whom he might have perceived as enemies or competitors, and in this context Crewdson is dead-on.

Another example of a misstep by Crewdson is his statement that the first human retrovirus to be isolated, HTLV-I, a cause of a rare form of leukemia, was first identified by Frank Ruscetti and Bernard Poiesz at the National Cancer Institute in Bethesda, Md. Although this statement is true, Crewdson ascribes no credit to Gallo for this discovery. Yet both Ruscetti and Poiesz were postdoctoral fellows in Gallo's laboratory at the time that this work was done. Crewdson surely knows that it is accepted procedure for the head of a laboratory to claim credit for research conducted on his premises by more junior scientists.

It is sad that these shortcomings detract from what is otherwise a compelling case that Gallo claimed and obtained recognition for research that had, in fact, been accomplished by the French. But what Crewdson fails to acknowledge is that the work conducted in Gallo's laboratory added new findings to those that had been published by the French and that the cumulative effect of the research efforts of both groups was to spur the field forward much faster than would otherwise have been the case.



CP

Robert Gallo speaks at a Vancouver AIDS conference in 1996.

LACK OF OBJECTIVITY

It is probably incorrect to state, as Crewdson does, that the in-fighting between the American and French groups slowed the development of a blood test that could safeguard the blood supply against HIV-1 contamination. In reality, both groups contributed to the development of such tests.

Further evidence of the author's lack of objectivity is the inference that Gallo may have personally unplugged freezers that contained stockpiles of viruses that he was anxious to destroy, so that other scientists could neither corroborate nor contest the validity of his results. And, in fairness, the implication that Gallo deliberately stole the French virus is impossible to prove. It remains entirely possible that sloppy research led to the contamination of cultures in Gallo's laboratory by the French HIV isolate that grew out and was later claimed by the Gallo laboratory to be their own.

Although this book describes the history of the first cases of HIV/AIDS in the United States in succinct fashion, it misses out on one of the most important aspects of the epidemic – the extent of human suffering that has been wrought by HIV throughout the world. The book makes little mention of the important issues of drug access, attempts to develop a vaccine against HIV-1 and the ability of the virus to mutate with amazing agility, giving rise to problems of drug resistance as well a wide array of HIV strains that differ from one another with regard to immunological makeup.

Simply put, this means that it may be impossible to design a single vaccine that will protect against all forms of HIV-1. The latter issue is so important that it ensures that HIV will continue to be one of the world's most important problems in public health for many years to come.

Although the roles of the French vs. U.S. scientists in regard to the research performed are well described, it is also probably unfair, in spite of his undeniable faults, to single out Gallo as the sole villain of the piece. Most scientists in the field concur that the leader of the French group, Luc Montagnier, was himself prone to fits of vanity in regard to his own role in the story.

The book also gets sidetracked by the personal lives of some of its leading characters, and Crewdson seems to take joy in describing the extramarital relationships of some of them. In reality, these tidbits of information only detract from the main theme – how the quest for scientific glory, if taken to excess, can do harm.

In summary, this book is a successful indictment of Gallo, whom history will probably judge to have been guilty of excessive zeal in the pursuit of scientific glory. However, there are certainly worse crimes and the fact remains that the research performed in the Gallo lab helped advance HIV drug discovery and the development of antiviral treatments that have enabled many hundreds of thousands of people around the world to live longer and enjoy higher quality lives.

Most scientists, even those who have large laboratories, are not prone to the types of excessive behaviour attributed to Gallo in this book. At the same time, most scientists would be happy to leave behind his long and distinguished legacy of scientific accomplishment.

✤ *Mark Wainberg is director of the McGill University AIDS Centre at Montreal's Jewish General Hospital and past president of the International AIDS Society. He is acquainted with almost all the scientists described in this book.*

2014 - Resume for Dr. Frank Ruscetti

[HL0040][GDrive]

Education:

- 1968 B.S. (Biology), Boston University, Boston, MA
- 1972 Ph.D (Microbiology), University of Pittsburgh, Pittsburgh, PA

Brief Chronology of Employment:

1972-1975 Research Instructor, Department of Medicine
University of Pittsburgh, School of Medicine, Pittsburgh, PA

1975-1978 Cell Biologist, Department of Cell Biology,
Litton Bionetics, Inc., Kensington, MD

1978-1983 Cancer Expert, Laboratory of Tumor Cell Biology
National Cancer Institute
Bethesda, MD

1983-1984 Cancer Expert, Laboratory of Molecular Immunoregulation
Biological Response Modifiers Program
National Cancer Institute
Frederick, MD

1984-1992 Senior Investigator, Head, Lymphokine Section
Laboratory of Molecular Immunoregulation
Biological Response Modifiers Program
National Cancer Institute
Frederick, MD

1992-2002 Chief, Laboratory of Leukocyte Biology
Division of Basic Sciences
National Cancer Institute - Frederick Cancer Research
& Development Center
Frederick, MD

2002-2004 Principal Investigator, Leukocyte Biology Section

Basic Research Laboratory

National Cancer Institute - Frederick

Frederick, MD

2004 -2013 Principal Investigator, Leukocyte Biology Section

Laboratory of Experimental Immunology

Center for Cancer Research

National Cancer Institute - Frederick

Military Service:

1964-1968 United States Air Force

Societies:

American Society for Microbiology

International Association for Comparative Research on Leukemia and Related Diseases

Human Retrovirology Association

International Society for Cytokine and Interferon Research

International Society for Experimental Hematology

American Society of Hematology

American Association for Cancer Research

Honors & Other Special Scientific Recognition:

- Andrew Mellow Fellowship, 1969-1972
- NIAMDD Consultant in Hematology Research, 1979-1981
- Member, Cell Proliferation Committee of Amer. Soc. of Hematology, 1983-1986
- Editorial Board, Experimental Hematology, 1986-1988
- Adjunct Professor of Biochemistry, George Washington University, 1988-2004
- HHS Distinguished Service Award for Biomedical Research, 1991
- Scientific Advisory Board, Guthrie Institute for Medical Research, 1991-2003
- Editorial Board, Experimental Hematology, 1994-1996
- Editorial Board, J. of Interferon & Cytokine Res., 1994-2000
- Editorial Board, Stem Cells, 1994-Present
- Award for Contribution to Human Retrovirology, Human Retrovirology Assoc., 2005
- Team Science Award Society for Immunotherapy of Cancer 2010
- Health and human services award for contribution to safety of blood supply 2012
- American Association of Immunologists Lifeline of Important Events: Discovery of interleukin 2, 1977

Research Interests:

Regulation of growth and differentiation of human leukocytes; biology and etiology of human leukemia; interactions of regulatory factors, chemicals, and oncogenic viruses with hematopoietic cells; tumor and viral mediated immunosuppression.

RUSCETTI, Maureen (O'Neill)

2017-01-18-the-boston-globe-pg-b8-clip-ruscetti

Of Brookline, Newton, Franklin and Popponessett Beach on Cape Cod, passed away peacefully on Sunday, January 15th, 2017, surrounded by her family, after a courageous battle with complications from type-1 diabetes mellitus, dysphasia and multiple strokes. She was born in Brookline on October 15, 1947, the daughter of Carroll O'Neill and Marjorie Ross.

Maureen was an active and well-loved graduate of Brookline High School, Class of 1965, and attended the University of Massachusetts, Amherst in pursuit of her BA. She was a student of life with a renaissance soul, a fierce advocate for the rights of the underdog whether person or animal.

Welcoming all to her world of arts and humanities, poetry and music, gourmet cooking and eating, she was also a gifted photographer, avid sketcher, devoted singer in the Sunday choir, staunch equestrian competitor with trusted mount Aja and loving guardian of all children. She believed children were God's gift to the family and could be seen doing the "Snoopy Dance" on the lawn celebrating every newborn. Everybody loved Maureen.

Nobody more so than Her Bob, devastated husband of 33 years, who must now walk the land without her by his side. Bob freely admits marrying way out of his league, Beloved son, Jonas Driscoll and wife Kerry, daughter Maddison, son Jack and Grandpa Mike of Sharon. Jonas has lost his greatest teacher and best friend. She is also survived by her siblings, sister Susan Yas and her husband "Sol" of Easton, sister Marjorie Clapprood and her husband Christopher Spinazzola of Boston, brother John R. O'Neill and his wife Martha of No. Attleboro, sister-in-law Barbara Sperrazza and family of Halifax and brother-in-law Frank Ruscetti and wife Sandra of Carlsbad, CA. Further survived by countless (grand) nieces, (grand) nephews, other relatives and friends.

A Mass of Christian Burial will be celebrated on Friday January 20, 2017 at 10:00 AM in St. Mary of the Assumption Church, 5 Linden Pl., Brookline. Visiting hours will be held in the Bell-O'Dea Funeral Home, 376 Washington St., BROOKLINE on Thursday January 19th from 3:00-7:00. Interment will be private.

There will be a memorial celebration of Maureen's life this coming summer on Cape Cod, which was Maureen's wish, details to come.

In lieu of flowers, donations may be made in Maureen's name to the Joslin Diabetes Center, One Joslin Place, Suite 745, Boston, MA 02215

GALLO

1991 (Jan 31) - Chicago Tribune : EX-GALLO AIDE CHARGED WITH EMBEZZLEMENT

Source : [HN010Z][GDrive]

John Crewdson, Chicago TribuneCHICAGO TRIBUNE

A former longtime deputy to AIDS researcher Dr. Robert Gallo has been charged with stealing $25,000 that a German pharmaceutical firm paid the U.S. government for biological research in the Gallo laboratory.

The former deputy, Dr. Prem Sarin, 57, was charged by a federal grand jury here last week with embezzlement and three other violations of federal law, including two felony charges of making false statements on financial disclosure forms.

Sarin is the second scientist from the Gallo lab to have been charged with criminal offenses by the U.S. attorney`s office here. Last year, Syed Salahuddin, another longtime Gallo aide, pleaded guilty to accepting illegal gratuities from a Maryland company that supplied the Gallo lab with services and materials.

Ties between that company, Pan-Data Systems, and another Gallo assistant, Dr. Dharam Ablashi, are being investigated by Richard Kusserow, inspector-general of the Department of Health and Human Services, according to sources familiar with that investigation.

Kusserow`s investigators are also conducting an inquiry into possible perjury and false statements by Gallo himself in connection with his prize-winning AIDS research at the National Cancer Institute in suburban Bethesda, Md., just outside Washington.

The cancer institute is part of the National Institutes of Health, which is an agency of the Department of Health and Human Services. Kusserow, who previously headed the white-collar fraud unit in the Chicago office of the Federal Bureau of Investigation, has oversight responsibility at HHS.

According to federal court files in the Sarin case, Sarin had tentatively agreed to plead guilty earlier this month to two lesser offenses. When that deal fell through, federal prosecutors asked the grand jury to charge the scientist with four violations of law, including embezzlement.

The offenses to which Sarin had agreed to plead guilty carry a maximum penalty of six years in prison and a $350,000 fine. The maximum for the four offenses with which he is now charged is 21 years in prison and a fine of $850,000.

Asked why his client had chosen to stand trial, Sarin`s attorney, W. Neil Eggleston, said only, "He`s innocent." Eggleston declined to confirm reports that Sarin had repaid the $25,000 that is the focus of the alleged embezzlement.

Other sources close to the case suggested that Sarin had withdrawn from the deal because of prosecutors` insistence that any plea bargain include some jail time.

Laboratory of Molecular Oncology

Molecular Basis for the Pathogenesis of Murine Retroviruses

Sandra K. Ruscetti, Ph.D.

Senior Investigator

Building FCRDC 469
Room 140
Phone 301–846–5740

Biography: *Dr. Ruscetti obtained her Ph.D. from the University of Pittsburgh and has been at the National Cancer Institute since 1975, where she began her studies on retroviruses in the laboratories of Wade Parks and Edward Scolnick.*

Research: The major focus of the research being conducted in this laboratory is to determine the molecular basis for the pathogenesis of retrovirus-induced leukemia and neurological disease in rodents. Three separate but interrelated animal model systems are being studied.

Erythroleukemia Induced by the Friend Spleen Focus-forming Virus
The erythroleukemia-inducing Friend spleen focus-forming virus (SFFV) encodes a unique envelope glycoprotein which alters the growth of erythroid cells by rendering them independent of erythropoietin (EPO). In order to understand the mechanism by which SFFV causes EPO independence, we have been studying the signal transduction pathways activated by EPO and determining how they are altered by SFFV. Our results indicate that several members of the Stat family of latent transcription factors are rapidly, but transiently, activated by tyrosine phosphorylation in response to EPO, and that the same proteins are constitutively activated in erythroid cells infected with SFFV. Studies are in progress to determine the mechanism by which SFFV infection of erythroid cells leads to constitutive activation of Stat proteins, and to determine whether the viral protein can activate other signal transduction pathways.

Leukemia Induced by a Myb-Ets-containing Retrovirus
The *gag*-myb-Ets-containing ME26 virus causes leukemia and anemia when injected into newborn mice. Our previous studies suggested that the virus was not transforming erythroid cells, but was causing leukemia by a unique mechanism involving the inappropriate activation of erythroid-specific genes in hematopoietic precursor cells. Studies undertaken to understand how ME26 virus induces EPO-responsiveness in hematopoietic cells showed that the viral protein transactivates the erythroid transcription factor GATA–1, and then cooperates with the GATA–1 protein to activate the EPO receptor gene. Studies are in progress to determine how the viral protein transactivates the GATA–1 gene, and how virus expression leads to the activation of some erythroid-specific genes, but not others.

Neurological Disease Induced by a Variant of Friend Murine Leukemia Virus
PVC–211 MuLV is a variant of the erythroleukemia-inducing Friend murine leukemia virus that causes a rapid neurodegenerative disease in rodents. We have been carrying out studies on this virus to determine the molecular basis for the change from leukemogenicity to neuropathogenicity. Our studies indicate that the envelope gene of PVC–211 MuLV is essential for its pathogenicity, and that there is a direct correlation between the ability of the virus to replicate in brain capillary endothelial cells (BCEC) and its ability to cause neurological disease. Studies are in progress to understand how replication of PVC–211 MuLV in BCEC results in the death of neurons. We have further shown that PVC–211 MuLV is unique among MuLV's in its

Studies are in progress to determine the mechanism by which SFFV infection of erythroid cells leads to constih1tive activation of Stat proteins, and to determine whether the viral protein can activate other signal transduction pathways .

Leukemia Induced by a Myb-Ets-containing Retrovirus

The gag-myb-Ets-containing ME26 virus causes leukemia and anemia when injected into newborn mice. Our previous studies suggested that the virus was not transforming erythroid cells, but was causing leukemia by a unique mechanism involving the inappropriate activation of erythroid-specific genes in hematopoietic precursor cells. Studies undertaken to understand how ME26 virus induces EPO-responsiveness in hematopoietic cells showed that the viral protein transactivates the erythroid transcription factor GATA-1, and then cooperates with the GATA-1 protein to activate the EPO receptor gene. Studies are in progress to determine how the viral protein transactivates the GATA-1 gene, and how virus expression leads to the activation of some erythroid-specific genes, but not others.

Neurological Disease Induced by a Variant of Friend Murine Leukemia Virus

PVC-211 MuLV is a variant of the erythroleukemia-inducing Friend murine leukemia virus that causes a rapid neurodegenerative disease in rodents . We have been carrying out studies on this virus to determine the molecular basis for the change from leukemogenicity to neuropathogenicity. Our studies indicate that the envelope gene of PVC-211 MuLV is essential for its pathogenicity, and that there is a direct correlation between the ability of the virus to replicate in brain capillary endothelial cells (BCEC) and its ability to cause neurological disease. Studies are in progress to understand how replication of PVC-211 MuLV in BCEC results in the death of neurons. We have further shown that PVC-211 MuLV is unique among MuLV's in its ability to replicate efficiently in capillary endothelial cells, and that as few as two amino acid changes in its envelope protein are responsible. This unique property of PVC-211 MuLV is now being developed for use in gene therapy targeted to endothelial cells.

Spacewar! on the Computer History Museum's PDP-1, 2007

Stephen Russell (born 1937)[1] is an American computer scientist most famous for creating Spacewar!, one of the earliest video games.

Biography

Russell attended Dartmouth College in Hanover, New Hampshire from 1954 to 1958.

Russell wrote the first two implementations of the programming language Lisp for the IBM 704 mainframe computer. It was Russell who realized that the concept of universal functions could be applied to the language. By implementing the Lisp universal evaluator in a lower-level language, it became possible to create the Lisp interpreter; prior development work on the language had focused on compiling the language.[2] He invented the continuation to solve a double recursion problem for one of the users of his Lisp implementation.[3]

In 1962, Russell created and designed Spacewar!, with the fellow members of the Tech Model Railroad Club at the Massachusetts Institute of Technology (MIT), working on a Digital Equipment Corporation (DEC) PDP-1 minicomputer.[4][5] Spacewar! is widely considered to be the first digital video game[6][7] and served as a foundation for the entire video game industry.[8]

He later served as an executive of Computer Center Corporation (nicknamed C-Cubed), a small time-sharing company in Washington (state). In the fall of 1968, he mentored Bill Gates and Paul Allen on the use of the DEC PDP-10 mainframe, while they were part of the programming group of Lakeside School (Seattle).[9][10]

2002 (Feb 28) - NYTimes - "A Long Time Ago, in a Lab Far Away . . ."

By John Markoff / Source - [HN01H4][GDrive]

STEVE RUSSELL sat in a darkened movie theater recently watching the army of credits roll by after a computer-animated Hollywood blockbuster.

There was a time, he recalls thinking, when a cutting-edge computer-generated fantasy could be conceived, written, tested and packaged for distribution in a few months, just through the part-time efforts of a small group of friends.

To be precise, that time was 40 years ago this month, with the result played out on a computer screen at the Massachusetts Institute of Technology. Two tiny spaceships were locked in mortal combat as they swung around a simulated sun. The duel was called Spacewar.

Designed by a small group of pioneering computer programmers led by Mr. Russell, it was the world's first video game. It was an early hint that a powerful new entertainment medium was on the horizon, one that would ultimately bond Silicon Valley to Hollywood. Perhaps most significantly, Spacewar

demonstrated that sheer fun would become a driving force underlying progress in computing technology.

Over the years it played a crucial role in inspiring the creators of companies like Apple and Atari, said Henry Lowood, the curator of Stanford University's collections on the history of science and technology. "It set off a chain of events that created companies and led to a whole idea of what Silicon Valley would be," he said.

It certainly established at least one stereotype of the high-tech age: a few frenzied geeks in their 20's obsessively laboring after-hours in a computer lab on a creation that combined play and programming.

But the premise of Spacewar seemed to reflect the specific preoccupations of that time in the early 1960's. It was completed the same month that John Glenn made the nation's first manned orbital flight. And the cold war was at its most perilous stage: the Berlin Wall had just gone up, and the Cuban missile crisis would soon follow.

Now those 20-something geeks are near or past retirement age. Unlike more recent generations of computing and Internet pioneers, Spacewar's six programmers did not find fortune from their invention. Their achievement has made them legends only within the fraternity of the world's original computer hackers.

"The only money I made from Spacewar was as a consultant for lawsuits in the video game industry in the 1970's," said one of the game's creators, Alan Kotok. "I have all this fame, but it's in a very narrow circle."

Mr. Kotok and the other members of the original team all remained part of that circle, pursuing careers in computers. Several became hardware designers, several went on to write software, one became a professor and one joined the secretive National Security Agency.

Their early creation is now a museum piece -- literally -- reflecting the software principles and programming culture of its era.

Designed to take advantage of the Digital Equipment Corporation's brand-new PDP-1 minicomputer and the advent of a cathode-ray display screen, Spacewar was written before software was patented, and the original programmers' instructions were shared and freely modified by a small group of software designers.

Introduced some months later at Decus, which was then a Digital Equipment Corporation users' group, Spacewar immediately attracted a cult following. It became so addictive that at the M.I.T. laboratory where it was designed, play was soon banned except during lunchtime and after working hours.

Spacewar was the original "twitch" game, requiring lightning reflexes. Each player used keyboard controls or a joystick to maneuver a tiny ship capable of firing a stream of torpedoes as it slid across the screen. Before long a "hyperspace" option was added so that a player could make his ship vanish and reappear at a random place on the screen, avoiding certain death.

Stewart Brand, founder of The Whole Earth Catalog, saw the game played by young hackers at Stanford's computer center in the early 1960's. "They were absolutely out of their bodies, like they were in another world," he recalled. "Once you experienced this, nothing else would do. This was beyond psychedelics. It impressed the heck out of me."

In fact, though they came to be known for their hours in front of a computer screen, the game's creators initially met through M.I.T.'s hiking club. The group was led by Mr. Russell, known as Slug, and Martin Graetz, known as Shag, both devoted science fiction fans who wondered why better science fiction movies weren't being made.

Another contributor, Peter Samson, then a 21-year old undergraduate studying engineering at M.I.T., added a crucial component called "expensive planetarium," an accurate scrolling star field that portrayed the night sky over Cambridge.

Spacewar began in January 1962 as a simple object-in-motion program, Mr. Graetz said, and by February had become a rudimentary game, including two ships, a supply of fuel and a store of torpedoes.

Both Mr. Russell and Mr. Kotok said it was never their intent to create a new digital entertainment medium. After the new Digital Equipment computer with its display was installed in late 1961, the group simply began thinking about what might be the best way to demonstrate the power of the new machine and hit on the idea of a graphical simulation of a battle between two spaceships.

Spacewar was an obvious choice, but no one in the group sensed what impact the program would have over a decade and a half of popularity.

"One of the things that drew me to the project was that here you could do interaction and painless education and demonstration, and it was engaging," said Mr. Russell, who was 24 at the time.

After agreeing to be the project's lead programmer, Mr. Russell said he procrastinated until Mr. Kotok drove to Digital Equipment and returned with a paper tape containing necessary math subroutines. Mr. Russell set to work by entering code on a Flexowriter, a typewriter device that translated commands into holes punched in paper tape.

Perhaps the most impressive feat was that Spacewar worked at all. The processor for the PDP-1 minicomputer ran at about 100,000 instructions per second, snail-like in comparison with the speed of today's fastest microprocessors, which exceed two billion instructions per second.

Moreover, the computer, which was built from discrete transistors, had to make the most of about nine kilobytes of random access memory, unfathomably little compared with the RAM of today's desktop machines, which can boast as much as one gigabyte -- a million kilobytes.

"Each new game tends to push the state of the art," said Richard F. Rashid, who heads research at Microsoft. "They stretch the machine as far as you can stretch it."

Moreover, the Spacewar program became an integral part of a spreading hackers' culture as it was carried on punched paper tape to the dozen or so research centers and universities that had the early PDP minicomputer.

"What I was most pleased with was that a number of people saw Spacewar and went off and said, 'I can do that' and then implemented their version on another system without looking at the source code," Mr. Russell said.

One of those inspired by the game was Nolan Bushnell, who went on to found the Atari Corporation. He was first seized by the idea of commercializing video game technology when he came across a version of Spacewar while a graduate student in engineering at the University of Utah.

In 1971 he introduced a version of Spacewar called Computer Space, which was [illegible]

In 1971 he introduced an arcade version of Spacewar called Computer Space, which was a commercial flop. Mr. Bushnell kept at it, though, and soon introduced the more successful Pong.

The game also made an impression on two other entrepreneurs-to-be, Steve Jobs and Steve Wozniak, the founders of Apple Computer, who as teenagers would ride their bicycles to Stanford's artificial intelligence lab, where the game was frequently played.

But credit for the first commercial video game actually goes to Bill Pitts, a Stanford graduate who with a high school friend, Hugh Tuck, installed Galaxy Game, a coin-operated version of Spacewar, in Stanford's student union several months before Mr. Bushnell introduced Computer Space.

It became a huge hit and was played by students for more than six years, allowing Mr. Pitts to pay back the $60,000 he had invested in the project. Today his version of Spacewar is in the collection of the Computer Museum History Center in Mountain View, Calif.

For his part, Mr. Russell, now 64, is only an occasional gamer. He visits arcades to keep up with video game technology and spends a couple of hours a month playing at his own PC. But his tastes, like the times, have changed. Now it is solitaire, not spaceships, that keeps him coming back.

The Crew Members

What Ever Happened to the Spacewar Six?

Forty years after its first shot was fired, the game Spacewar can be experienced on the Web at agents.www.media

.mit.edu/groups/el/projects/spacewar. Here is what became of the M.I.T. programmers who created it:

DAN EDWARDS -- A cryptography expert, he joined the National Security Agency.

MARTIN GRAETZ -- Joined the Digital Equipment Corporation shortly after working on Spacewar and became an early expert on diagnostic software.

ALAN KOTOK -- Became a computer hardware designer at Digital Equipment, where he worked for 34 years. He is now associate chairman of the World Wide Web Consortium, which develops guidelines for Web technology.

STEVE RUSSELL -- Moved to Stanford University, where he specialized in tools for artificial intelligence research. Now works at the Nohau Corporation, a Silicon Valley company that makes computer design tools.

PETER SAMSON -- Works at AutoDesk, a design-software company, where he helps develop three-dimensional modeling tools that are used extensively by computer game companies.

WAYNE WIITANEN -- A mathematician, he worked at General Motors researching neural nets, circuits that mimic the way nerve cells are connected in the brain. He is retired.

Correction: March 1, 2002

A caption in Circuits yesterday with an article about the 40th anniversary of the first video game misstated the name of the game. As the article noted, it is Spacewar, not Spacewars.

http://wordsbloom.com/uploads/files/Hard%20Drive%20-%20Bill%20Gates%20and%20the%20Making%20of%20the%20Microsoft%20Empire%20%281%29.pdf

As it turned out, the real world called them first. And what a deal it was—all the free computer time they wanted.

Founded by four University of Washington computer experts in the fall of 1968 with the backing of several Seattle investors, Computer Center Corporation was a private Seattle firm offering the largest concentration of timesharing computer power on the West Coast. The company (which Gates referred to as "C-Cubed") had leased several computers from Digital Equipment Corporation, including a PDP-10 like the one Gates and the other Lakeside students used.

Computer Center Corporation attempted to sell its timesharing services to scientific and engineering businesses in the region—or any other customer in need of computer power at an affordable price.

One of the firm's founders and chief scientific programmer, Monique Rona, had a son in the eighth grade at Lakeside—the same grade as Gates. She knew about the school's teletype machine and its deal with General Electric for computer time. A representative from her company contacted Lakeside to inquire whether the school would be interested in making a similar arrangement with Computer Center Corporation. The students would have an even greater opportunity to learn about computers, the representative argued.

http://wordsbloom.com/uploads/files/Hard%20Drive%20-%20Bill%20Gates%20and%20the%20Making%20of%20the%20Microsoft%20Empire%20%281%29.pdf

Space Wars became the mother of all computer games. Before long, a generation of new games followed.

At Stanford, Russell worked on multi-user computer systems, using DEC s PDP-6. C-Cubed was created to take the next version of that multi-user system, the PDP-10, and make a commercial service out of it. Russell was recruited by the C-Cubed company from Stanford's Artificial Intelligence Research Center in late 1968 because of his experience with multi-user computer systems.

Russell sometimes gave Gates and Allen computer manuals, with instructions to return them the next morning. Instead of going home, the boys would remain at C-Cubed all night reading.

Paul Allen and Bill Gates "got a big part of our start in computer science through the University of Washington when we were still students at Lakeside School," said Paul Allen in announcing his $14 million commitment to the UW Department of Computer Science & Engineering. "UW Computer Science & Engineering is an engine of opportunity, and we want to help make sure it's an even more cutting-edge resource for coming generations."

DEC PDP-10

SDS Sigma 5

Burroughs B5500

Control Data Corporation 6400

The Computer Center Corporation, a timesharing startup founded in the late 1960s by UW faculty and staff (including Computer Science & Engineering professor David Dekker and graduate student Dick Hamlet), made PDP-10 time available to Lakeside students by means of a teletype terminal.

Gates and Allen also utilized four computers on the UW campus -- an SDS Sigma 5 operated by Computer Science & Engineering, a DEC PDP-10 operated by the Medical School, and a Burroughs B5500 and a Control Data 6400 operated by the Academic Computer Center (now Computing & Communications).

During the 1980s, the University of Washington employed an exceedingly apt slogan in radio spots: "UW: You get something, whether you go there or not." Indeed! Research universities contribute to their regions in many ways -- some explicit, and some serendipitous.

The recent commitments of Allen, Gates, Microsoft Corporation, and dozens of other individuals and organizations to the UW Department of Computer Science & Engineering ensure that UW CSE will continue to lead and to serve long into the future.

2009 (Aug 08) - Stephen Russell Interview at Computer History Museum

Source : [HI001H][GDrive] / Text copy : [HI0028][GDrive]

Interviewed by: Al Kossow

Recorded: August 9, 2008

Al Kossow: We're rolling. It's August 9th, 2008. This is Al Kossow we're in Mountain View, with Steve Russell. Thanks for coming by.

Steve Russell: You're welcome.

Kossow: So I wanted to start with early history. So where were you originally from and what was your family like?

Russell: I was born in Hartford, Connecticut. My father was an engineer; my mother was a teacher turned housekeeper.

Kossow: What sort of engineer?

Russell: Mechanical. He told me a bunch of stories, on his knee.

Kossow: Oh, okay. So where did he work?

Russell: He worked for the Hartford-Empire Company which became part of Emhart, which is still around in a much different incarnation. They built glass machinery, and he had worked on building and installing annealing lehrs, which take the hot glass fresh out of the mold and heat it up again to the point where it oozes but doesn't fall down, you hope, and then cool it down very slowly, which relieves the stresses and makes it possible for the glass to survive. If you don't do that, if you just take it out of a mold after it's been molded and let it cool down quickly, the glass becomes very fragile, like the demonstration, Prince Rupert's Drops and Bologna bottles, where you just do something very small to it and it explodes.

Kossow: So did he end up going around the country when they were installing these?

Russell: He did a fair amount of field work. He also had several patents on construction details for lehrs. He worked on automatic control systems, which at the time were vacuum tube chart recorder systems where a chart recorder would record something and provide control signals to control it. And he also worked on installing the actual molding machinery and giving advice on the operation of the glass furnace, which at the time— and I think it's still true— but at the time the construction of the glass furnace was there would be a large central furnace, maybe 50 or 100 feet in diameter, and the raw— the batch that was going to be melted, would be put in there, in one side, and then there were long tunnels, called feeders, which took the glass out of the central furnace and heated it up to— or cooled it down, as the case may be— to exactly the right temperature for molding, and ended up with a device that would drip glass and cut off pieces of red-hot glass and send them off to molding machines. It took something of the order of five or ten days for the batch that went into the furnace to actually get out there to the far end of the feeders where it turned into bottles. But it was— what went in affected what went out, and so there was a considerable element of back magic involved in figuring out when things weren't coming out right, at the far end, what was wrong somewhere along the way.

Kossow: Did you have any siblings?

Russell: What? No.

Kossow: There was no siblings.

Russell: My father grew up in Worchester. He was born in 1898, so he grew up in Worchester around the turn of the 1900. And he told me stories about that, and one in particular that I remember is he was— one of his things was when he was a kid he went down to a foundry, which was relatively close to where he lived, and learned about the engines and what was in the foundry. It occupied two city blocks, one for the foundry and one for the machine shop, and it had its own power; it had a 300 horsepower Corliss engine, and that ran the whole two blocks of the factory. The biggest load was the blower on the cupola.

Kossow: It was all electric?

Russell: No.

Kossow: Well the mechanics—

Russell: Belts and line shafts.

Kossow: Oh, okay.

Russell: With a line shaft that went over the street that separated the two blocks of factory.

Kossow: Okay, so it was a single motor driving the entire—

Russell: Yes.

Kossow: So this would've been in—

Russell: 1905 maybe, somewhere around there. And one of the— in the, well I think, sometime between 1945 and 1948 his company acquired the Pitkin Governor Company who had been making steam engine governors for— and governors for anything, for that matter.

Kossow: Like fly ball governors?

Russell: Yes. Which had a factory somewhere near Hartford, I don't remember exactly where, and they were shutting down the factory because it was woefully obsolete; namely, it had a central steam boiler and steam engine and everything in the factory ran off line shafts. And they had a beautifully maintained Corliss engine, and the last day they were operating it my father got me in and I got to see it. The reason they were operating it on a Saturday was because the manager was cleaning out his office, which was on the second floor, and he was kind of lame, so they had to keep the elevator running.

Kossow: Oh, and it was all driven off a common—

Russell: And the elevator was run off clutches off the line shafts.

Kossow: So was that one of the last Corliss engines running in Connecticut?

Russell: I don't think it was the last.

Kossow: No.

Russell: But I don't know. It was certainly very late for a Corliss engine. They did have electric lights, but there was no sign of electric motors. And it was very interesting because it was very quiet. Even though there was sort of some belt noise, which was just occasional flapping and a tick as the—

Kossow: The leather belts.

Russell: Yes, a tick as the splices went over the pulleys, but the Corliss engine itself made no noise at all when it wasn't putting out any power.

Kossow: So when did you get interested in trains?

Russell: I don't remember, and I'll tell you why.

Kossow: Did you do a lot of train traveling?

Russell: Something which I've been told about, and which there are pictures of me, is when I was about three, we took a train across the country to visit my mother's folks— **my mother's father and her sister and brother-in-law in the State of Washington**. So that was a long train trip, which I don't remember. But the picture shows me lying down on his living room floor looking admiringly at his O Gauge model, which was running on track on the floor. So I was definitely interested then, but I don't remember it, and the next Christmas he gave me a Lionel train set, and I haven't recovered. And that was— I got interested— well I liked running the trains. When I got to be around ten somewhere, I'm not sure exactly where, I started getting interested in signals and doing more elaborate layouts and that sort of stuff, and that's what got me started getting interested in electronics. **And then my father got laid off in, I guess the end of 1948 or the beginning of 1949, and my folks decided to move out to the State of Washington and go into farming with my grandfather.** And we made a long auto trip out of that. We went down south and around and covered almost all the extant narrow gauge railroads at the time: the East Broad Top, the East Tennessee and Western North Carolina, the Denver and Rio Grande and— that was about it; we didn't cover the California and Sierra Railroads.

Kossow: So you father was a big train fan then too?

Russell: Well he was tolerant at least.

Kossow: Oh. Oh, so he was doing this for you.

Russell: Yes.

Kossow: So you'd just try to visit the track or actually try to get rides?

Russell: Yes. Well in some cases they were still carrying passengers and in other cases they were— the crews were susceptible to begging.

Kossow: So you'd hop on and then your parents would meet you.

Russell: Yes. So anyway my parents, my father went into partnership with my grandfather, which didn't work out very well and lasted less than a year, and then we moved up to a small farm in Burlington, Washington. And so I went to Mount Vernon High School, which was near Burlington, and when we moved— I started my freshman year in high school when we were in Mount Vernon, and when we moved to Burlington I kept going to Mount Vernon High School. And I had some friends. My friends were mostly interested in electronics and radio and that sort of thing.

Kossow: Did you get a ham license then?

Russell: No, I got a ham license much later, much, much later, but I let it lapse. But I learned in high school a great deal about radio and World War Two radar because there was plenty of surplus World War Two radio and radar around. One of the guys who was a little older than I was, not much, was an avid ham and his equipment tended to be made by butchering, really crudely, surplus radio gear. One of the things— his favorite metal working tool was an ice-pick.

Kossow: Ugh…

Russell: Which tended to leave volcanic holes in the aluminum chasses but it was effective, when wielded with enthusiasm.

Kossow: Okay, so then did you end up getting a scholarship to go to Dartmouth, or how did you end up back on the East Coast?

Russell: Well my aunt married- my father's sister married G.W. Pierce [NOTE : See https://en.wikipedia.org/wiki/G._W._Pierce , George Washington Pierce article on Wikipedia] , who was a Harvard professor, and they felt that everyone should get a proper education, and so she paid for my tuition. Uncle George was a— started out as an acoustics expert, and in the 1930s he studied the acoustics of sound waves in quartz and how you could use the sound waves in quartz as a resonator for electronic oscillators; the Pierce oscillator circuit was one he designed. And he then went off— one of the things that he showed me one time when I was visiting, in the late forties, was— in fact there were several things on that visit. One was a closet in the Applied Science Laboratory where he had attempted to build a pendulum clock that would compete in accuracy with the crystal clock. But it wasn't successful, the crystal was still better, but it was an electrically driven pendulum in a vacuum chamber and quite elaborate. **The same visit he also took me to see Harvard Mark I, which was busily printing tables for something or other, and Professor Aiken showed us around, and he checked to see what it was doing and decided he could demonstrate the error detection feature.**

> *[NOTE : See The https://en.wikipedia.org/wiki/Harvard_Mark_I , the Wikipedia article for "the IBM Automatic Sequence Controlled Calculator (ASCC)" . Side note : "as a general purpose electromechanical computer that was used in the war effort during the last part of World War II. One of the first programs to run on the Mark I was initiated on 29 March 1944[2] by **John von Neumann**. **At that time, von Neumann was working on the Manhattan Project**, and needed to determine whether implosion was a viable choice to detonate the atomic bomb that would be used a year later. The Mark I also computed and printed mathematical tables, which had been the initial goal of British inventor Charles Babbage for his "analytical engine".]]*

And so he put his finger in one of the typewriters so that it kept a number from striking, and there were contacts on the typewriter that noticed whether the numeric keys had actually completely hit, and so that rang a bell and caused operators to come out of their offices and so on. And they were also— down in the basement they were working on an electronic machine, but that wasn't nearly as interesting and apparently it wasn't working yet.

Kossow: So that would've been the Mark II.

*[NOTE : See https://en.wikipedia.org/wiki/Harvard_Mark_II : "The **Harvard Mark II**, also known as **Aiken Relay Calculator**,[1][2][3] was an electromechanical computer built under the direction of Howard Aiken and was finished in 1947. It was financed by the United States Navy. Howard Aiken and Grace Hopper worked together to program and build the Mark II."]*

Russell: Two or three, I'm not sure.

Kossow: The first drum calculator.

Russell: So I thought that was interesting.

Kossow: And so was that your first exposure to computing?

Russell: Other than just doing- learning math, or learning grade school math.

Kossow: Automatic computation.

Russell: Yes, yes. Well let's see, had I— I had seen adding machines before.

Kossow: But there was no machines up at Dartmouth yet?

Russell: Oh no. My senior year at Dartmouth, 1958, '57, '58, I worked on the most advanced data processing operation that Dartmouth had, which was a card shop with a 402 or 403, the slow tabulator. And that had just been installed in the last year or so.

Kossow: Okay, so here it is, it's 1958, and somehow or other you get hooked up with John McCarthy.

Russell: John McCarthy was— in '56, '57, and maybe a little earlier— was a professor at Dartmouth. And he had arranged to get the SNARC.

> *[See https://en.wikipedia.org/wiki/John_McCarthy_(computer_scientist) : John McCarthy (September 4, 1927 – October 24, 2011) was an American computer scientist and cognitive scientist. McCarthy was one of the founders of the discipline of artificial intelligence.[1] He co-authored the document that coined the term "artificial intelligence" (AI), developed the Lisp programming language family, **significantly influenced the design of the ALGOL programming language, popularized time-sharing,** invented garbage collection, and was very influential in the early development of AI. McCarthy spent most of his career at Stanford University.[2]]*
>
> *https://medium.com/interesting-histories/john-g-kemeny-inventor-of-basic-f0d118c9f2f4 : "Kemeny completed his doctorate in 1949, aged 23, for a dissertation on "Type-Theory vs. Set-Theory". He also completed his marriage, wedding Jean Alexander from coastal Maine, USA, of whom we will hear more later. Kemeny was appointed to the Dartmouth Mathematics Department in 1953, four years after his dissertation — and within two years' time, he had already become its chairman. It was there that Kemeny met Thomas Kurtz, another PhD from Princeton, who had taken a pay cut to work at Dartmouth and was looking for ways to increase his income. Kemeny suggested an IBM research fellowship at the MIT computing site nearby. This happened in the summer of 1956. The computer and cognitive scientist John McCarthy had arranged a course in "artificial intelligence" — probably the first time that the term was ever used in a course. "]*
>
> *WHY DOES RUSSELL NEVER MENTION - KEMENY ?*

Marvin Minsky built the stochastic Neural Analog Research Computer, which was an electronic rack about this big, a tabletop rack, which was attempting demonstrating an electronic mechanism for doing learning the way it was thought that human nervous systems did, and it was a bunch of vacuum tube, relatively straightforward vacuum tube electronics, and you connected them randomly when you got the— and you would put a pulse in and then you got

something out maybe. And when you got a result you liked you said, "Yeah that's good," and that caused all the neurons that had fired in the last operation to crank their little pots, probability pots, up higher. And when you said, "No that's bad," it caused the ones that had fired in the last operation to crank their probability pots down lower. And this was done with— they remembered whether they had fired, and what that did was cause a magnetic clutch to pull in, and then the reward or punishment was done by turning a- by a motor running for a bit to crank the pots over a little.

Kossow: And they all changed by the same amount.

Russell: Yes. Much later **Minsky (see https://en.wikipedia.org/wiki/Marvin_Minsky)** fought the Perceptron wars and apparently proved that that couldn't do it. **And so I had worked on that, and McCarthy, John McCarthy had arranged that, and he offered me a job at MIT working on computers, which he thought I could handle. The summer— I didn't fulfill all of my graduation requirements. I was supposed to produce a senior thesis but I never got around to it. That summer I had a job in summer stock at the Berkshire Playhouse in Stockbridge, Massachusetts, which at last observation was still running, under a different name. I had been quite active in theater work in college, and I was student technical director of the Dartmouth Players my senior year.**

Kossow: So this was stages and props and lighting.

Russell: So I spent the summer in summer stock getting paid $25.00 a week plus board, or plus room rather. The room was in the basement under the scene shop, not a particularly wonderful place but it didn't rain— well it didn't rain there often. Well when the— there was one incident where the scene designer had gotten enthusiastic with washes where you'd put all the flats down and then throw a big bucket of colored water on them. And it turned out that he did that one Saturday, and that got all the beds kind of wet down in the basement. We were not happy.

Kossow: So there was more than just you down there.

Russell: Oh yes. Yes, well it was some of the apprentices and the rest of the technical crew. Anyway—

Kossow: So you got through that.

Russell: Yeah, we got through that. Well actually I learned a lot and— no I actually had fun at it.

Kossow: Did you do much theater work after that?

Russell: I did a little when I was working at MIT but not too much. Computers were more absorbing, at the time anyway.

Kossow: So you get to MIT then, it'd be—

Russell: The fall of '58.

Kossow: So at that point they had the 704.

Russell: At that point they had the 704 installed and running. I had worked the previous summer— actually I had worked at MIT for John, and he sent me to work using FORTRAN, which was just out of the box, and I did a little, some matrix inversions and some other stuff in FORTRAN. So I sort of knew my way around there. Anyway, when I arrived— I don't remember the detailed sequence of who did what but my impression is that John had figured out the basic machine language code for CAR, CDR and CONS, on the 704, and had—

Kossow: So he had in mind what the basic atoms of Lisp were going to be at that point.

Russell: Yes. I'm pretty sure— he may have had garbage collection in mind but I don't remember that it was mentioned first off, but it came fairly- it came sometime that fall. And it was abundantly clear, from later events, that no one had thought through garbage collection completely at that point. So anyway we started writing some sample code. We did list input and output routines and maplist and a few other of the standard functions; I don't remember the other ones, but we had written all those in assembler.

Kossow: So this is just you and John working on that.

Russell: No, there was— Klim Maling was another full-time employee, and there were several students and grad students associated with it one way or another. I don't remember their names but there were a couple who were seriously thinking about compiling Lisp, at least by December they were. And we were certainly very conscious that it would be a good thing to compile Lisp, although it was much easier to write an interpreter. And given the size of the 704 it was probable that compiled code would have given even less space for free storage. So compiling wasn't on the high priority list.

Kossow: So just to give a background of what was going on at the time, there was John working on developing Lisp, and that was in which department? So what was going on around him at the time?

Russell: I think that was in electrical engineering. John and Marvin had started the artificial intelligence project I guess that summer; so the summer of 1958, something like that.

Kossow: What building was it in?

Russell: Building 26, and I think Building 26 was mostly electrical engineering. We started out in a dungeon in the basement next to the coin machines, which was echoy and noisy. We later on moved up to the second floor. So anyway we had been, Klim and I some of the students, had been hand assembling, or hand compiling, Lisp M-expressions for map list and print and read and that sort of thing. And my remembrance is that John sort of came in one day, in late September or October or something like, that with the universal M-expression, that is the Lisp interpreter written out as an M-expression, and we sort of looked at it and said, "Oh yeah, that'll work," and I looked at it and said, "Oh, that's just a matter of doing more hand compiling, like I've been doing. I can do that."

Kossow: So that's how the first one was bootstrapped.

Russell: Yes.

Kossow: Just by hand.

Russell: And actually most of the code is probably in still in the Lisp 1.5 listing. But I got something working before Christmas, which was a useable interpreter; no garbage collector, but there weren't any big programs yet. And my remembrance is that in the beginning of December or so Jim Slagle, a blind grad student, had a seminar where he explained how he was planning to do formal integration in Lisp, and he started writing his Lisp expressions on the

board, or getting them on the board somehow, I don't remember exactly how that was done. But he had no trouble understanding Lisp and writing Lisp, but he used a Braille typewriter. There was no connection between that and the machine so somebody had to read the output to him. And I, and I guess Dan Edwards— I think Dan Edwards was an undergraduate at the time, I'm not sure— and a couple of the grad students who were worrying about how to compile Lisp were sort of sitting in the back, and he wrote something and then it had a clever double recursion in it, and we sort of started muttering, the interpreter can't handle that. What happened was, the initial version there was a problem with something like maplist where there was a functional argument. And the problem was if the functional argument had a variable by the same name as one of the internal variable's in maplist, that actually— if it was all interpreted— that was actually visible on the association list, the A list, then inside the functional argument you would see the map list version of the variable name before you'd see the intended version, which was out in the outer call to maplist. And so anyway we had been using a dodge like defining a function- or using internal variable names like terribly unique program variable, and it was clear that with this double recursion that wouldn't work. And so there was a great deal of muttering—and, I think I invented it, I'm not sure; I'm sure it got critiqued by plenty of other people— what we fixed on what was generally called the function funarg hack where when the functional argument got passed a map list, it got extended with- it got transformed from the function to funarg, which had the function and the current A list at the time of binding. So what happened in the machinery of map list or whatever else was churning around with the functional argument wouldn't be visible to the internal function when it actually got called. And at the time we thought it was a rather despicable thing, and we didn't like it all because it was going to be hard to compile. Nowadays there's a lot more patience for things that are hard to compile and a lot more memory to use for such things. But it worked, and so it stayed and— oh, and also no one ever suggested a better idea. I don't remember— I believe the garbage collector was proposed in the fall of '58 and I don't think we started— I don't remember when we started working on it seriously. I wasn't— I guess it started in parallel with the second version of the interpreter which had the function funarg hack. That got working sometime in the spring of 1959. And the other project was to get- was to make the garbage collector work. And one of the things which became evident much, much later, as garbage collector bugs kept showing up for years and years, was that it would've been a really good idea if we had segregated the storage for list structure, and the stack for list structure, from other kinds of storage that weren't involved in garbage collection. But we hadn't and so what we did was make up a table of all the locations where list structure could be stored and use that to interpret the stack— let's see, I think we also must have had a template for the function. So anyway so there was a list of all the places where list structure could be stored and a way of determining what things on the stack were list structure and what were not. And it turned out that those lists were not fully correct, because they were made by hand by reading the code, and so for at least a year, and I think longer than that, we would periodically get bugs where somebody had done some perfectly innocent function and had gotten the free storage list tacked in the middle of its list structure, because something that shouldn't have been garbage collected was. So I'm sure that we hadn't thought that out when we had fixed the programming conventions.

Kossow: So you had something sort of working then in the spring, '59?

Russell: Yeah, I don't think we had the garbage collector fully functioning in the spring. I think that wastook another while.

Kossow: So were there very many people trying to use the language at that point? Because you said somebody was trying to do integration with it.

Russell: I think there were of the order of five or ten serious grad students, and John inflicted it on his Introduction to AI class, and so there were a bunch- there were maybe another 20 more or less student users. And I'm not sure exactly how big— I don't remember exactly when this happened and how big the user base was at the time. But sometime later John figured out that CAR and CDR weren't really good names. And so he tried to launch a program to call them FIRST and REST, which seemed like much better names. And I remember supporting this and trying to help in it. But it didn't work. There were too many entrenched users who were used to CAR— had internalized CAR and CDR and didn't want any change. And I don't know how many there were at the time but it couldn't have been more than 50. But the damage had already been done. I'm reminded of the original, the landline Morse code story. When Morse first developed the telegraph he had— there were, some words had long spaces in them and there was a long dash that was assembled, and it very early became evident that this led to transcription errors. The original Morse receiving instruments were siphon recorders.

Kossow: What's that?

Russell: Ink siphon, recording on paper tape, driven by clockwork. But after the first year or so they realized that the operators weren't bothering to keep the ink supplied, because they were listening to the tink-tink of the recorder and recording it directly, writing it down, having learned what the tink-tink sounded like. So then they said, "Okay, we don't need that," and they built the “modern”, that is, the telegraph sounders that are around, which were simply designed to sound like the siphon recorder. After about ten years or so, when Morse telegraphs were being expanded to Europe, they had to revise the character code to handle some of the European characters, and at that point they eliminated the long dash and the inter-character long spaces, and they tried to persuade the U.S. operators to adopt that. [Shakes his head ‘no’] And so landline Morse kept its intra-character space and long dash until the last landline Morse circuits were shut down. Same problem.

Kossow: Yes. Now just so that it's on here, CAR and CDR come from—

Russell: Contents of Address Register and Contents of Decrement Register.

Kossow: Which are two registers in the 704.

Russell: They are two fields in a 704 instruction, and because they were used for indexing— they're used in the indexing instructions— and because they were used for indexing there were special load instructions which would load either address or decrement into the accumulator. So this made it easy to do instruction in CAR and CDR. And that was the reason— that was clearly an effective way to do list structure, and that was the reason they were called that. There was also another—

Kossow: John had come up with that?

Russell: Yes.

Kossow: Those two functions?

Russell: And we had no problem thinking about it that way for the first year or two. It was only after trying to teach it. Another feature of the indexing instructions on the 704 was that they used two's complement arithmetic and so the number that you wanted to store in the list structure was actually the two's complement of the location in memory that you were pointing to, and it turned out that made— <video breaks up > <Crew talk>

Kossow: All right, we're rolling. So this is tape number 2 of the Oral History of Steve Russell. So we're at mid-1959, MIT. So at that point, you're concentrating mostly on working with John on Lisp. At that point, had Jack Dennis gotten the TX-0? So what's going on? Computing at MIT at that point, was this 704 by 1959?

Russell: 704 but not much else; Whirlwind, I guess, in the fall of 1958 or 1959—

Kossow: That's when they were shutting it down.

Russell: They were shutting down Whirlwind, and since a bunch of people in the Computation Center had worked on Whirlwind, they arranged some tours of Whirlwind. And I took one of them, and one of the things I remember was the "bouncing ball" program. Now, much, much later I have gotten the impression from reading some of the Whirlwind literature that somehow that was felt to be very important. I think it may have been a benchmark for Whirlwind's ability to do real-time stuff, but I haven't seen any direct evidence of that. But there's some indirect reference that—

Kossow: So was this running on the large scope?

Russell: This was running on a large scope; this wasn't one of the Cape Cod scopes. That was still classified. But this was running on a scope that was in a rack by the operator position. It was more or less the size of the PDP-1 scope, it may have been a little bit smaller. The PDP-1 scope is 10 inch, I believe. It's 9.25 inches diagonal, x and y size for the display area. At any rate, the bouncing ball display— there was a wall and a floor that was drawn. The floor had a little hole in it. The ball started off on the top of the wall. I don't remember whether it was just a single spot or whether it was round or something more. But anyway, the ball got pushed off by an unseen hand, and it fell down and bounced on the floor, in smaller and smaller bounces, showing that the physics were correct, and it either bounced off the edge of the screen, or it bounced into the hole and went down through the bottom of the screen. And when it went through the hole in the bottom of the screen, it then stopped changing the amount of force it got pushed with. So you got push… bounce, bounce, bounce, bounce… push a little harder… bounce, bounce, bounce, bounce… push a little harder yet… bounce… bounce… bounce… boip! And they had a speaker on Whirlwind, and so it made relatively distinctive sounds for the bouncing. I don't know how they contrived that, whether they contrived that, or whether that was just the way it worked; but it did come with sound effects.

Kossow: So did you just get a tour of the control room and the Flexowriter array area? Or did you actually go into the computer itself?

Russell: We went into the computer itself, but they kept us on the main pathways. It was live; it was 300 volts exposed on those racks. It wasn't a place where you wanted a large mob.

Kossow: So, were there fans above it, cooling? I'm just curious as to how loud it was inside.

Russell: I don't remember an impression that it was loud. Of course, I was used to 704 computer rooms, which weren't exactly quiet, and tab shops, which weren't quiet. But by the data processing standards of the day, I don't think it was loud. I think they had air conditioning and ducting, but I don't remember for sure. Anyway, there was more stuff to do on Lisp, and we worked on Lisp for a while. I don't remember anything about TX-0 appearing. **At some time around, I think it was 1961, late 1961, early 1962, I had gotten bored with working on Lisp and got a job at Harvard. And part of that involved my not having a deferment anymore, so I went into the Army Reserve, and I think—**

Kossow: So you had had a deferment while you were working for John?

Russell: Yes. I'm not clear on the exact sequence of events— anyway, I started working for Harvard; I had to go off for six months of active duty; I came back, management had changed; new management was not nice, and—

Kossow: So you didn't stay at Harvard very long?

Russell: No. And when I came back from— **about the time I was convinced that I didn't want to continue working for Harvard, John was moving to California, to Stanford, and offered me a job at Stanford, which I took. So I ended up at Stanford in the fall of 1962.** But, popping back a little earlier, when I was working at MIT, I got active in the model railroad club and continued to be active when I was working at Harvard, and a number of the people in the model railroad club were associated with Jack Dennis's lab, and TX-0 and the PDP-1 when it arrived in 1961. I don't know exactly when TX-0 got going, but it was going noticably at least a year or more before the PDP-1. That had a display. It had roughly the same complement of I/O gear that PDP-1 had, and you could write similar type programs with it; it wasn't quite as fast, but it was transistorized.

Kossow: So was Jack's lab in Building 26, too?

Russell: Yes, it was also on the second floor of building 26, just down the hall. One of the things— a missed opportunity in the museum setting up its PDP-1 restoration display I thought, was that it would have been very easy to recreate the building 26 décor, which was painted cement block and tile floor. Probably not as interesting as the mural of the production line.

Kossow: Trying to pretend it's The Mill.

Russell: Anyway, the PDP-1 arrived, and Marvin Minsky wrote the tripos demonstration, generally called the Minskytron, and there was the famous weekend where the mob of undergraduates transcribed the macro assembler from TX-0 to the PDP-1, because they didn't like FRAP. And then fairly quickly thereafter, they wrote DDT and connected up the macro symbols to DDT. So that was all sort of in place by the middle of the fall of 1961. And the combination of the Minskytron and having DDT with interactive debugging with symbols was very tempting. I don't remember the exact order of things, but I'm pretty sure I started talking up a better demonstration program than the Minskytron, and eventually, Alan Kotok went up to Maynard and collected the sine and cosine routines from DECUS, presented them to me, and said, "Okay, here are the sine and cosine routines; now what's your excuse?" And I discovered I had run out of excuses; I had to actually think. And so I started work and figured out the basic trick of Spacewar! display which is that you only need to calculate a unit vector pointing in the direction of the spaceship. And you can express everything else the spaceship does, and the outline of the spaceship in terms of that unit vector, suitably scaled. So it's basically a lot of addition in the usual program upkeep.

Kossow: Do you want to just give an overview, then, of how Spacewar! actually works?

Russell: It's one big loop, and the loop is on the displayable objects. And I called them displayable objects, although I didn't know about object orientation or object-oriented programming at the time.

Kossow: So you have the sun—

Russell: Colliding objects, not displayable objects. The colliding object is a space ship, there are two of those. And that has a lot of extra data with it. It shares the position and velocity tables with all of the torpedoes and explosions that are running around. So there's just one big loop through the colliding objects, and it looks at all the higher-numbered colliding objects to see if there's a collision, using an octagon because you don't need to calculate the square root of anything, you can do that by work on X difference, Y difference, and X+Y difference—

Kossow: So the bounding box for the collision detection is an octagon?

Russell: Yes. So it goes through, it sees if this object is colliding with any higher-numbered object. If it is, it replaces the calculation routines. That's another thing that every colliding object has, is a calculation routine. It replaces the calculation routine with the explosion calculation routine. And then things take care of themselves. Then, after it's decided whether it's an explosion or not, it goes off to the calculation routine. And the calculation routine updates the position, since all colliding objects have velocity; and if it's a spaceship, it worries about reading the controls and updating the other things about the spaceship in deciding whether to launch a torpedo or not. And if a torpedo needs to be launched, it searches up the colliding object table for an empty slot, indicated by having no calculation routine. It searches up the table for an empty slot, puts a torpedo calculation routine there, and the spaceship position plus the suitable increments, so it won't run into its torpedo, and of the velocity of the spaceship plus an increment for the torpedo, and it goes on. When that the main loop gets done, you go off and do some star display and display the sun, and calculate — and part of the spaceship calculation is to calculate the effect of gravity on the spaceship. Originally, there wasn't any gravity, and I had an interpreter, which interpreted the outline description, and Dan Edwards, sometime in late 1961 or early 1962, looked at that code and decided if he could write a special purpose compiler which would compile precisely the right code, and proceeded to. And there's one compiled outline for each spaceship; each spaceship actually does half of the spaceship outline and then you twiddle the vectors and do the other half. That keeps the display running just as fast as it can. That gives time to calculate the effect of gravity on the two spaceships, but not on the torpedoes. So we decided that they were photon torpedoes not affected by gravity.

Kossow: So when the explosion routine starts, it continues calculating motion, so the explosion moves?

Russell: Yes. If you see two spaceships collide, if you watch closely, you will see that there are two explosions that continue off in the direction that the two spaceships were going. There is another number in the table for all colliding objects, which is the size. And this is, roughly speaking, proportional to the amount of computing it takes to compute that object. And at the end of the loop, as you go through the main loop, you accumulate the sizes also; and so at the end of the loop, there's fritter away time loop that attempts to keep the frame rate approximately constant. It doesn't do a wonderful job; it's visually adequate, but God help you when you try to take a movie of it.

Kossow: One of the complaints with all modern, little kids trying to play it now is that it's TOO SLOW.

Russell: Kids who are used to something like Asteroids seem to think that. But when we do the demos, we get a number of people who seem to be still quite addicted to it with the old, slow version. Now, that was always a complaint; the reason that all the parameters got accumulated in the first page of the listing, which says you can put that first page of the listing of the console, and anyone who wanted to try a different set of parameters could. But the ones that were compiled in or assembled in were the ones that I thought were good. Now it turns out I'm not a representative arcade game player, and so my version of the parameters is slower and gives more opportunity for marksmanship than the arcade version.

Kossow: Right, that's the whole thing with gravity and doing the, what's that called, where you whip around the sun? Does it have a name, where you whip around the sun and you shoot?

Russell: The closest name is the "CBS maneuver" is what happens when two lazy experts fight each other, which is they both turn at right angles to the sun, and fire for 3.5 or 4 seconds, so they're now in stable orbits, and they know it. And then they turn at each other and start trying to place torpedoes where they think the other one is going to be. And so the trails turn into an eye around the sun, and CBS used that as a logo, so it got called the "CBS maneuver". One of the spaceships can go the other way around the sun, so that both ships meet on the same side of the sun. But that seems usually to have less chance of winning. Not much less, but somewhat less.

Kossow: It's better that you stay on opposite sides, then?

Russell: Yes.

Kossow: And then at some point, you added hyperspace?

Russell: Yes, and we realized that that was going— I don't remember whether we actually had it. I may have had it for a little while with no limit, but it became very clear that someone who didn't understand could use hyperspace to escape their proper justice forever, and so we added the unreliability of hyperfield generators very quickly. One thing that Asteroids and the arcade versions, the later arcade versions of Spacewar! added, which actually was a big help, especially with their high acceleration rates, was “training mode” where space was actually viscous. So if you got your ship accelerated so that it was going across the screen so fast you couldn't understand what was going on, if you took your hands off, the situation would gradually become understandable. I don't think I would have been persuaded to do that in the original Spacewar! because it was “unrealistic.” But it definitely made it easier to learn.

Kossow: So are there any other favorite anecdotes about Spacewar!, or just the spread of Spacewar!?

Russell: Well, the "imitation is the sincerest form of flattery"— many people saw Spacewar! as, some people ask for copies of the source, and of course we gave them out because we very briefly considered trying to sell Spacewar!. We realized the only possible customer was Digital Equipment, and we also, on a little reflection, that they were too cheap to do it. So we gave it out to anyone who wanted it, and some people got the listing and thought about it, and by reading it— a lot of people simply saw the game and had a computer that wasn't the PDP-1 but did have a display, and implemented Spacewar! their own way. I suspect most of them figured out the “basic trick”, but I'm not sure.

Kossow: What “basic trick” were you thinking of?

Russell: That you could do everything based on the spaceship unit vector. How are you fixed for the source code for different implementations of Spacewar!?

Kossow: We have a few. I don't know if we have the PDP-10 version. We have the 12 version, and I think we have a PDP-7 version.

Russell: I think Bob Saunders wrote the PDP-7 version. I think one 6 version simply ran on the PDP-1 simulator. I think there must have been others, but I don't know. Something for some history grad student to pursue. When we were running a demo for the Yelp event, there was one woman who had done Spacewar! in turtle graphics as a high school programming project, which she wasn't too happy with. She seemed to like the demo of the original Spacewar!.

Kossow: So turtle graphics running on a micro or something like that?

Russell: I didn't quiz her. I didn't have the opportunity to quiz her further.

Kossow: So she thought this version was better?

Russell: No, she just thought it was nice to see the original.

Kossow: So she was in her mid-20s?

Russell: 20s or early 30s; probably 20s. The DEC field service story where the DEC production people got into the practice of loading Spacewar! the last thing before PDP-1 shipped, and field service would then unpack it, make sure that nothing horrible had happened, tried turning on power, and starting Spacewar!. And if it worked, they would call the customer over and say, "See, it works." If it didn't work, then they'd worry about it. In the restoration project, we had a little reflection and we decided that probably if Spacewar! works, just about everything works, as far as machine instructions go. It doesn't guarantee all the I/O gear works, but it does multiply and divides, and just about every instruction. So a lot of people implemented Spacewar! just from knowing that it existed and having seen it maybe once.

Kossow: Were there any other interesting hacks you remember from back then, at MIT? There's all the TMRC train stuff.

Russell: Yes, under the layout provided, the TMRC had developed a telephone equipment scrounge method, which consisted of the Western Electric Educational Gift Program. The things that Western Electric was giving away to educational institutions came out in a catalog toward the end of the school year. So for years and years, TMRC members would go over to the electrical engineering department supply room and get a copy of the catalog and look to see what they thought the layout could use, ask for it, and then Freddie Broderick, who ran some part of that, got a station named for him on TMRC, would then duly request it from Western Electric, and most of the time it would come through. So there was a carefully sorted store of relays and switches and general electrical stuff, telephone quality, under the layout, which got used for making parts and layout, and also got used for the first two versions of Spacewar! controls.

Kossow: Those were the three-way lever switches?

Russell: The version that I remember quite clearly, and nobody else does, so I think they must have died very early— there was a 1930s design, 4-pushbutton block that was used for buzzing buzzers in an office; so you'd have a receptionist who had maybe one or two or three lines on a phone and when one of them rang, she'd pick it up, find out who it was and then buzz the buzzer to get that person to pick up the phone. Those were nice because you could hold them in one hand and play them like a flute. But they died very quickly; they were designed for being pushed a few times a day, and it turned out that there was a fatigue problem when they were pushed hundreds of times a day. And so they died fairly early. Then somebody, it may have been Bob Saunders, made up the second version, which is the one that's Shag sketched and everyone remembers, which is a wood box with a slanted masonite top, and a left-right-off switch, and up-off-down switch, and a pushbutton. And that was used for rotate left, rotate right for the horizontal one, accelerate or fire torpedo for the up down one and hyperspace for the pushbutton.

Kossow: And were quiet enough that you couldn't tell what the other guy was pushing?

Russell: Yes. They were switchboard type switches, so they didn't click; also the first ones didn't click. And one of the problems with clicking switches, which is what people tend to start with, is you could tell when your opponent is out of torpedoes or rockets because you hear the switch clicking and nothing is happening on the screen.

Kossow: So most of the play, then, was done with the lever switches?

Russell: Yes.

Kossow: So the exhibit that we have isn't really accurate with the pushbuttons?

Russell: No, but those are genuine— those are clicking arcade type pushbuttons. But usually when we do the demo, the demonstrators don't get to the point where that matters. Occasionally, it does. But the improvised quality of the control boxes is quite authentic, and they always were pretty improvised.

Kossow: But they've held up pretty well. It's been running for two years now, and haven't had any problems with the boxes?

Russell: No, in fact, there have been occasional problems with the cables, but given the craftsmanship of the original cable construction, that's not surprising.

Kossow: So go back to 1962, then, when you came out to the west coast?

Russell: Yes. At that point, they were building what was then the computer center complex; I forget the names of the buildings, but anyway. Eichler of Eichler Homes was building them. We were scrounging for— we had some time on a 7090 down at IBM San Jose somewhere. I don't remember exactly where, but we had weekend or nighttime time. So we did a little work on Lisp, and—

Kossow: So this was all 1.5 at that point?

Russell: Yes, and John also had the idea that we could build, we should build a display-based timesharing system using PDP-1 and what we would we could get with custom displays. And he and Pat Suppes worked up a joint proposal to do this. I don't remember the exact dates on that, but at any rate, it arrived, and we also got custom displays from Philco. That took a while, to do the request for proposal and evaluate that sort of stuff.

Kossow: This is all coming out of ARPA funding?

Russell: I think so, I don't remember. Stanford should have it all in their archives somewhere.

Kossow: So how many people were working with John, then at that point? You had come out, so you were working for him full time?

Russell: I don't remember. There was the usual herd of grad students. It wasn't a big herd; I think it was the order of four or five. I don't remember if there was anyone else full-time. I think there were, but I don't offhand remember who all they were. The PDP-1— one of the things that DEC figured out— I'm not clear on who did the pushing on them; I suspect some combination of John and Ed Fredkin provided a lot of the motivation. But DEC figured out that they could build a swapping drum which would replace the contents of 4K of PDP-1 memory in one drum revolution, which meant that the drum had to be 4000 words around, and the data rate had to be a little slower than the 5 microsecond memory of a PDP-1. It was about 8 microseconds, I believe. And because the drum was 4000 words around, you could start the transfer at any point to the appropriate words, to the appropriate address and have it wrap around and end up in one revolution without any latency penalty. That was the basis for doing the PDP-1 timesharing system, the idea being that you'd get a 16K PDP-1, you'd have 12K for system, and 4K for user, and then you could swap users in and out. Part of that was there was a computer science department committee, which included Niklaus Wirth, sort of blessing the operation, the design, and so on. And Wirth was very insistent that the keyboard should include modifier keys. I remember that I resisted this idea; I believe John did, too. But Niklaus Wirth was very insistent.

Kossow: And what did he want to use the alternate sets for?

Russell: He felt that modifying the meaning of a keystroke would be a good additional control mechanism. I don't remember his exact detailed argument. And since they were just contacts, it wasn't very expensive to put them in so it was easier to put them in. And of course as soon as they started working, everybody started using them, and they've been on the keyboard ever since.

Kossow: So this was in addition to the normal control keys.

Russell: No, in addition to the normal shift key. These were essentially an ordinary typewriter keyboard.

Kossow: Right, because they weren't ASCII yet.

Russell: Yes.

Kossow: So why was he [Wirth] called "Bucky"?

Russell: He was very enthusiastic. He got the nickname Bucky Beaver. I don't know exactly the history of that.

Kossow: Just eager beaver.

Russell: Yes.

Kossow: So they were called “bucky bits”?

Russell: Informally.

Kossow: The modifier [keys]. So they were a separate bit in the encoding?

Russell: There was a space bar. There was a space bar, which was sort of at the bottom of the keyboard, and they were just square buttons, maybe just a key and half space off from the ends of the space bar, one on each side.

Kossow: And then when they came back from the display, they were just extra bits that got tacked onto the encoding.

Russell: And since the PDP-1 system— they seemed to be quite useful for editing and the like on the PDP-1 system, so when MIT AI was doing new keyboard system, they imitated it, and they may have added another one. But at any rate, they never fell off the keyboard after that.

Kossow: All right. Well let's take a break. It's a couple minutes to go on here, let's head on into tape number three.

Kossow: This is tape number three of the oral history of Steve Russell. You were just getting the PDP-1 time-sharing system going at Stanford, and you had just gotten the Philco displays.

Russell: Yeah, and we got them going. Philco did custom displays.

Kossow: Were the displays in a room adjacent to the 7090 and the PDP-1?

Russell: The displays had a central controller that was almost as big as the PDP-1. And they had big cables that went out to 12 displays. I think the cable length could be something like 100 to 150 feet. It was one off. **It was done by Philco military people.** It was very high performance for the time, not nearly as high performance as was originally promised, but high enough. It could do text much better because in addition to a high performance deflection system, it had an analog character generator system. So there was a digital memory for the strokes involved in making a character, but an analog system that produced high-speed but small deflection signals to actually draw the character on the screen at the current position. And being high-speed analog being pushed as hard as it would go, the printing— the character set, the first time people looked at it, was nearly unreadable. However, after a week or so, you get used to it just like getting used to somebody's handwriting, and so it was no particular problem, wasn't too satisfactory. And the overall speed of the system was not what was promised, and in fact the negotiations over the final price with Philco started out with, well, the system seems to be performing at about half the speed, so we think it's worth about half the price. <laughs> Things went on from there. But at any rate, they didn’t make a terrific lot of money on it, that's for sure.

Kossow: Could it only draw characters or could it do graphics as well?

Russell: It could do graphics also. It had a vector generator which could cover the whole screen. The reason the graphics were fast was because they just covered a character position. And I think they had a separate deflection coil for the characters. So there was a gross deflection and then a character deflection. But we could run 12 users and the response was pretty good. And you could run 4K PDP-1 program. And it was six…

Kossow: What sorts of programming did you do on that system?

Russell: Other than working on pieces of the various operating systems that we tried to do for it and spending an unhappy summer evening— several— many, a couple of months of unhappy summer evenings debugging the IBM 1301 disk interface, the only thing I really did was a 3-D flight simulator. I didn't do all of it. I think, let's see— Bill McKeeman wrote a program he called GOGOL which was a compiler, a sort of ALGOL 58 compiler, which in fact fit in a 4K PDP-1 and compiled code that fit in a 4K PDP-1. And he provided the flight equations and we had a little— and I think I provided the scenery, which was lights. And so we had a program where you could fly a simulated, real plane. And the landscape consisted of a field with runway lighting and it was night, so there was a town with a grid street display next to the air field. So everything was done with sequences of lights on a line, uniformly spaced lights on a line with a perspective view so as that they gradually disappeared in the distance. And that was instructive but not the— as a game it wasn't too much fun because it was too much— it was very slow-paced. Now, that's realistic. The rate at which things go on in an airplane when it's going crosscountry and not going very fast isn't very fast. But it's a lot more interesting when you can turn around and look at the countryside than when you're looking at a screen and it's night. <laughs> So, that was interesting, but not a good game.

Kossow: The start of the CRT-based text editors were on those though, right?

Russell: Yes, and in fact <laughs> we had— I didn't do the text editors but I was certainly in on the text format and the way things worked. It turned out that we had a pretty good text editor, eventually. We had one problem in that if inserted a lot in the middle of a text file or at the beginning of a long text file, it would provoke copying, recopying the whole rest of the text file to provide some space. The basic storage idea was you had the standard read text routine, which would read a block from the disk. And the block always had the information about how much of the block was actually in use. So for text reading, you would read the block, pick up the word count or— and go that far. And you knew when you got that far you had to go to the next block. So the reading was reasonably as fast as you could do it, but you didn't have to fill the block completely. And so the meta-information, which was the pointers to all the line beginnings, was stored in the top of the block. And there was some more notes in the blocks so as it, I think it started, there was a pointer than said how far

beginnings, was stored in the top of the block. And there was some more notes in the blocks so as it, I think it started, there was a pointer that said how far that extended at the top of the block. And then the space in between was for expansion of the text. And that way, by knowing where all the lines began, we could get reasonably fast searching. And by having the block normally starting out half full, there was room for a lot of editing without requiring any copying or anything. You could just read the block, edit it and write it back or maybe read the two adjacent blocks, edit them and write them back.

Kossow: So these blocks were being swapped in from the 1301 disk?

Russell: The 1301 or— yeah.

Kossow: The drum was just used for swapping or was there a file system on there too?

Russell: I don't remember how it was distributed. There was some file system available on the drum. But it wasn't all that big. I forget, was it 32 files? I don't know. I think there's a brochure for it running around loose somewhere, but I don't remember. May have been just 16 files, but that's still a four files over for non-swap, not involved in swapping. <laughs> As that system got going and with— six displays were for computer science department, six were for Pat Suppes' programmed instruction studies. And when that system got going it had the <laughs> most trying computer bug I've ever had to deal with, which was "the drum with two beginnings". This drum, you know, had a counter which kept a position. And when the system got to be used heavily, what we discovered was every now and then it would— programs would get really trashed and looked like they'd just been relocated— we looked carefully and eventually figured out that it looked like they'd just been relocated in memory. So the right code was there, but it was in the wrong place. And a bunch further detective work indicated that the drum was sometimes screwing up the locations where it was swapping the addresses. And…

Kossow: Did it appear to be swapping on 4k boundaries?

Russell: It was still doing 4k boundaries, but it was just relocating the 4k that was swapped into different addresses, modulo the 4K. Well, there was much weeping and a great deal of study. Of course this only happened when it was in heavy use. So we had to whip up a diagnostic to show it, which we managed to do. And then we called in the DEC and Vermont Research who had made the drum and they determined, oh, it seems there are two beginnings to this drum sometimes. Turns out, the way they got the index mark was they had one track reserved for the index and one track reserved for clock. And what they do is write a single transition on the index track, which was the beginning of the drum, and then write 4,000 words, 4,000 pulses around the drum and twiddle the frequency of the writing when they were writing the clock track, so as that there was some gap, but not a very big gap between the end of the 4,000 words and the beginning. And they'd always start writing when the index results came around. And that was fine. But it turned out that when things were very busy and there was lots of writing, you were doing writes and reads at the same time, in some cases, there would be enough cross-talk to generate a spurious index pulse, which would zero the counter.

Kossow: How did they get around the problem?

Russell: They moved the twisted pair that carried the index pulse signal carefully away from everything else. But that was a long saga, because it took at least a week, I think it may have been more than a week, to get it all sorted out. And there were lots of people standing around, you know, when is it going to be fixed? When is it going to be fixed? And to debug it you needed the whole system.

Kossow: So you had to run it really hard and then you could put a scope on the index and every once in awhile see this erroneous pulse.

Russell: Yeah. And this is before the day, you know, with the modern storage scope there'd be no problem. But this was the days when you put a hood on the scope and twiddled… <laughs>

Kossow: And tried to see the extra little thing that isn't there very much. The learning group kept using it after John moved off to the PDP-6?

Russell: Right.

Kossow: So that was about 1965?

Russell: Something like that. I don't remember the times. You know, I was busy with setting up the PDP-1, herding the PDP-1 maintenance and at the time then, we got the D. C. Power Lab and there was a bunch of setting up with that and getting the PDP-6 to work. As I say, I don't remember the times, but the PDP-6 was more or less working, and I left in about '68 I believe.

Kossow: I was just reading John Markoff's book and the whole story about how the D. C. Power building happened, and that there's nothing inside of it, and there was no air conditioning…

Russell: Oh yes, there was air conditioning. There was the Great Mother Of All Air Conditioners. <laughs> No, the central air conditioning had been provided and there was a 300 ton, a BIG 300 ton air conditioning unit down in the basement. And that was always fun for us because— well, usually it was fun. When it didn't work, it wasn't fun. Anyway, it eventually, because it was so big, we started calling it the great mother of all air conditioners or GMOAC. <laughs>

Kossow: So was it a central unit supplying the whole building?

Russell: Yes, the whole building.

Kossow: But it wasn't enough air conditioning with the 6 in there and everything else?

Russell: Oh no. No, it was designed on the idea that it was offices. And a big computer room with that vintage computer was a lot more than offices. And of course offices, you know, had a desk and a light. It didn't have a computer on the desk. The neat thing about the basement was, it was a partial basement and was all concrete. And it was curved, the building was curved, so it was sort of a science fiction location. And taking people down there and leading them into this room with this giant green machine was sort of surreal. We liked taking people on that part of the tour.

Kossow: So you ended up having to shuttle a lot between campus and there?

Russell: Yeah. And eventually I ended up at the, in the Power Lab.

Kossow: So you overlapped with Les [Ernest] for a couple of years?

Russell: Yes, yeah.

Kossow: What did you end up working on out at SAIL?

Russell: Mostly herding maintenance and connecting peripherals and that sort of stuff. There was plenty of maintenance to do on a PDP-6. We had,

generally had one or two technicians to help with that but I was supervising that. You know, there were lots of things happening.

Kossow: Widgets being built and robots running around?

Russell: Well, and we were debugging hardware while the time-sharing system was running, which was periodically exciting for all concerned.

Kossow: Do you have any interesting Dave Poole stories?

Russell: <laughs> Let's see. I don't think I was there. I wasn't very aware of the tree house. What was it? I don't remember. <laughs> The PDP-6 was stretching the technology, it turned out. It wasn't planned to be, but it was. And so many things in the PDP-6 were marginal for one reason or another. One thing that was marginal was the memory bus, which was DC, marginal at DC at full length as— in hindsight what I say now is that the notion of noise margins was not well developed at the time those circuits were designed. I don't think they calculated noise margins AT ALL. At any rate, there was an additional problem in the memories that we had, which was that they had— they were built with the latest two-sided technology at the time, which involved, at the time they were designed, which involved eyelets instead of plated through holes because plated through holes weren't considered reliable and probably weren't reliable for quite a while. I wasn't exposed to early unreliable plated through holes. It turns out the eyelets were brass. And the idea was, you put the eyelet through the board and you just crunched down and flanged it out. So, on the side you had a eyelet that was flared out at about a 45 degree angle and a piece of etch running up to it. And when it got soldered, you had a solder fillet in the, between the eyelet and the etch. But it also turned out that the coefficient of thermal expansion for circuit board and brass was not the same. So as the system heated and cooled, there was always a little push and pull. Now, solder doesn't behave well under tension, and under repeated stress tends to fatigue and crack. And the cracks tend to corrode. And it turns out that lead oxide or tin oxide or some combination of them makes a poor but intermittent diode. And so <laughs> the essence of the thing was that the memories kept developing cold solder joints. And so we ended up with a program of doing what we called running mechanical margins. I revealed the method of running mechanical margins to the PDP-1 restoration group a year or so ago, and they were amazed. They just weren't familiar with this. Anyway, what we did was we would run the memory diagnostic and start tapping gently on all the boards in the memory that had this problem. When the memory diagnostic rang the bell to say there was a memory error, then we'd start localizing the tapping to try and locate the board. It turned out you could do this fairly reliably. And the alternative would have been to take the computer down for something over a week and redo all the joints, which was a really big job. And we concluded it was better to run mechanical margins for a couple hours once a week than do that. And what we'd do is we'd…

Kossow: So you just take the handle of the screwdriver or something, just tap on them?

Russell: Tap gently. Because, if you tapped on the back of the board that had the problem, you'd get pretty consistent failures and it you tapped on its neighbors, it wouldn't be consistent. So then we'd pull the board and redo the connections on that board. But it was kind of laborious because the fix we used was, we'd take a piece of copper wire, we'd clean out the solder in the eyelet, we'd take a piece of copper wire and run it through the eyelet and then solder it on both sides. And so then when the eyelet stopped conducting, it didn't matter. But there were like 40 of those on a board, so— and there were, you know, lots of boards on the machine, so it was ugly. And as part of this, the system programmer decided that I needed to be alerted whenever there was a memory problem. And so whenever the system detected— they fixed it so whenever the system detected a memory error, it rang the bell on every teletype in the building. <laughs> So there was no escape. And this was when all of the office terminals were teletypes. So it was…

Kossow: How long did it ring it? For, like, a minute or just once?

Russell: No, just once for each error. At any rate, because of this memory intermittence, there was— we did have problems on acceptance test too, or DEC had problems on acceptance test. And Bob Clements was the DEC engineer who herded the acceptance through. I don't know whether he was still working in field service. He started working in DEC field service and he went on to engineering fairly quickly. But anyway, he was herding the acceptance and because the memories were so intermittent, we kept finding memories problems and reasons not to. And eventually, the final acceptance involved Dave Poole stomping up and down on top of the memories and having the memory diagnostic continue to run without reporting any errors. <laughs> It was a nice high computer room, so you could easily stand on top of the boxes and jump up and down or stomp. I don't think he was jumping up and down, he was stomping.

Kossow: How big of a hardware crew was there back then, a dozen people? How many people were at SAIL when you left in '68?

Russell: I think there was like 25 or 30 offices. I'm not sure. You know, some of them were two or three students to an office, some of them were individual. Let's see. What was it? There was a technician for sure, and usually another engineer working on hardware and on some combination of maintenance and hooking up new stuff, because there were various arms and TV camera and other things getting hooked on. So…

Kossow: So by the time you left, you weren't really doing much programming at all?

Russell: No. And when I left, I went to work for a startup in Seattle called Computer Center Corporation. And there it was some amount of herding the DEC hardware people and a fair amount of customer training and some helping with applications-type programming, but not much programming.

Kossow: Were they KI10s by that point or KA10s.

Russell: No, KA10s. This was the first round of time-sharing startups, Applied Logic and CompuServe, and Computer Center was a little late in that but essentially the same group.

Kossow: So where did they come out of?

Russell: University of Washington computer people, mostly, and me and Dick Gruen from variously DEC and Stanford. The . . .

Kossow: Did they end up adding any special hardware to the KAs?

Russell: No. <laughs> The communications hardware was really special. I forget what it was called. It was the Straight-8 with the bit banging teletype hardware attachment instructions.

Kossow: The DC01? It wasn't the 680.

Russell: Maybe it was 680.

Kossow: Okay. So it was like a 32-channel teletype multiplexer?

Russell: But it was done by adding, in essence, a "receive one bit and transmit one bit" instruction to a PDP-8. And so the software had to change the base address, do the instruction and then change the next base address. And I forget the horrible details, but at one point I wallowed in them to try to put in five-channel teletype code, to mix five-channel and eight-channel in the same line, which was in principle possible, but in practice very hard. That was GENUINE

PDP-8 programming, where you look the— <laughs> you got these…

Kossow: Count the cycles?

Russell: You had the assembler listing with all the timings and you kept adding them up and worrying about it. But the thing that was especially memorable about that was the console. The PDP-8 was a Straight-8, installed on a rack, but still a Straight-8. And we had a problem with static control in the computer room. I think they didn't put any humidification in originally, and we also had some cheap plastic chairs in the computer room. And at one point in the middle of winter, I remember sitting on the chair in front of the stopped 680 and getting up and having the chair go zap, zap, zap, zap to the strips at the side of the floor tile, and sitting down and having it go zap, zap, zap, zap again, and watching the PDP-8 program counter increment. So to keep things running, we had the— during the daytime we insisted on no shoes in the computer room. And <laughs> don't get anywhere near this PDP-8. We also had a giant Bryant. This was the big giant— the big Bryant moving head disk there, first moving head disk which had a hydraulic actuator and…

Kossow: All these vertically stacked platters.

Russell: Yeah. That was not as reliable as was desirable. But the main struggle was we just didn't get enough business. And so eventually they went out of business. And at that point, I guess I had annoyed DEC sufficiently that they thought maybe I would be useful in marketing. And so I started working for Digital.

Kossow: There's the one little story that you had a couple of testers up in Seattle.

Russell: Oh yes, yes. We did have a testing program. Was it TOPS-10 by then? I'm not sure. At any rate, the multi-user operating system for the PDP-10 was not a paragon of reliability. In fact, it started out with a pretty dismal mean time to failure. And so we had a couple of people working on basically fixing, full-time, fixing bugs in the operating system. And there was no real lack of bugs to fix. Monique Rona had— was one of the principles, and her son was going to Lakeside School. And so she arranged that we could— we give some time to the Lakeside School who had got a teletype. And we also had built a training room which had six or eight terminal teletypes in it. And what we would do is on Saturdays especially, we'd open that up to the Lakeside students to come in and load test the computer. We wanted lots of people. And the rules were, you can do anything you want, you can try to break the system if you want. But if you do manage to break the system, you've got to tell us what you did and don't do it again until we tell you. And this was quite fruitful. We collected heavy load bugs this way. And two of the students were Paul Allen and Bill Gates. And they had to be admonished several times about the "don't do it again until we tell you" part of the rules. But they certainly had a great deal of fun and they evidently learned quite a bit.

Kossow: You remember anything in particular that they did?

Russell: No. They asked lots of questions. And one of the things that we would do at Saturdays was, Dick Gruen or I or somebody would be in the terminal room, or periodically stick our nose in the terminal room, make sure that the pandemonium was under control, and answer questions.

Kossow: So how many terminals did you have in the terminal room?

Russell: I think it was six or eight. The idea was, you'd use it for doing training classes because we were training people and using— I think we had BASIC by then. **There was one professor at the University of Washington was using computer time who was very annoying. And I had sort of heard of his reputation. I hadn't dealt with him directly when he started. But I got him a couple of times, and knowing his reputation, I had somehow set my mind that I was not going to be annoyed by him. And I managed not to be, which was a little surprising, and I tended to have relatively short patience. And so since I didn't <laughs> run away, I'd swear never again when I talked to him, I got him for, as— you know, if he had a call it got to me very quickly. And eventually, we got to be quite good friends and he was— we got along well. But it was mostly because I had decided for some reason that I just wasn't going to let him annoy me. Now, I don't usually do that, and I've not done that a number of times since when it would have been a good idea. But…**

Kossow: But you managed to get through it. So would this be 1972, 1973 then when you went to DEC?

Russell: Yeah. I started in DEC I think in late '69 or '70, something like that.

Kossow: So the time-sharing business didn't stay around very long then at all?

Russell: No. Well, it managed to operate, it turned, out nine months after its net worth was zero, which was rather amazing.

Kossow: Just ended up not paying the bills for…

Russell: Yes. Well, you know, those things like travel agents and…

Kossow: But you were out of there by then?

Russell: Well, no, I was around, sort of, as a spectator, as a bemused spectator, sort of preparing for the next paycheck not to appear.

Kossow: That's what I was wondering, if they stiffed you for your pay. You managed to get out of that.

Kossow: All right. This is tape number four of the world history of Steve Russell. **So we're launching into your career at DEC.**

Russell: Well, let's see. I started out in PDP-10 marketing, which translated as maybe marketeer. And what that translated to was running benchmarks and explaining sales pitches of a certain amount of system configuration. And I started out in building 5 in the mill of 5/5. Let's…

Kossow: So this was still before the KI10 came out? They were still selling KAs?

Russell: I don't remember the exact phasing of which…

Kossow: Because it was right around then when the KI10 came out. Did you end up going on field trips a lot to customers?

Russell: Not a lot, but some. And one of the more memorable disasters was Bonneville Power Administration— actually it turned out quite well. But Bonneville Power Administration was looking for a central computer to gather together the data and to run predictions. Because Bonneville Power is the federal agency that runs most of the power dams in the Columbia Basin starting with the Grand Coulee. And one of the problems that they wanted to optimize was when they— the water storage is almost all upstream in Grand Coulee and a couple of other dams up at the headwaters. And so once they let water out of Grand Coulee or the other storage reservoirs, the water goes down to the sea sort of irresistibly over a period of about 48 hours. And what they want to do is optimize it so that they don't let any water go over the spillway and get wasted on the way, they want to go through turbines and generate power. And so by regulating when they— how much water they use in which dams, they can try to optimize it so that the head is

turbines and generate power. And so by regulating when they— how much water they use in which dams, they can try to optimize it so that the head is the maximum and yet none of the water goes over the spillway.

Kossow: Were they worrying about peak demand then, as well?

Russell: Yeah. They knew what their demand pattern was. But they also wanted to keep track of what was going on in real-time for reporting. And so they had a real-time benchmark. And I was one of the guys working on the benchmark. And one of the things we had to do was time a number of things. And so we got the benchmark running, the usual style, late at night, and came the big demonstration. And we started it, started running the benchmark, and things were all right for a bit. But then it started coming up with negative elapsed times for some of the tasks. And we scratched our heads a little and figured out oh, it was because one— we were triggering one of the start or stop, I forget which from one— from the internal crystal clock and the other one from the power line clock. And so when the power line clock was slightly off when they were making up for the power line having gotten slow, then we started getting the negative elapsed times. Well fortunately, Bonneville Power understood that explanation. And so as we were— the two of us were sort of commiserating after the long demo and trying to wind down, the salesman came bouncing in and said, "Hey boys, you're in real luck. I persuaded them to give us another chance," to which our reaction was, "Oh, shit," <laughs> because we got to work our ass off for ANOTHER two weeks.

Kossow: So you switched everything over to the crystal clock?

Russell: Yeah. We fixed the timing problem and ran the benchmark. The benchmark worked fine. They bought the system and much later the salesman gave me a tour of the Bonneville Power Control Center so that worked out all right after all. But it was memorable, and continued my education on benchmarking.

Kossow: So then you stayed in marketing support for a couple of years?

Russell: Yeah. Wasn't too much too memorable other than that, I think. I did herd a product through the process. It wasn't a very big product. There was a remote printer for the 10 systems, which had PDP-8 and a card reader, and a printer, and some Teletypes on it.

Kossow: Ran over a synchronous line?

Russell: Well, yes. And the printer was inexpensive and had a cam instead of a— this more or less standard paper tape— wide paper tape carriage control unit like the IBM printers have. And I wrote it up something like "a vertical format preset to 11-inch forms." And I guess I did a pretty good job because the salesman on the account that was complaining, that wanted to run checks or something like that called up and said, "Does this mean it does what the customer wants?" I said, "No. It's just describing what we have and it still doesn't do what the customer wants." But at least the salesman read it. Dick Gruen's [ph?] joke was, "He was never sure that the salesman read any of the technical material, but he's QUITE sure that they knew every detail of the commission plan." Of course the DEC commission plan was very simple. There wasn't any.

Kossow: So the salesmen were always straight salary?

Russell: Yeah, which has benefits but had its disadvantages, too. The DEC sales force was clearly not in the IBM league, and the IBM sales force certainly had a commission plan. But one of the things that I've noticed is that IBM was very careful to use their very best salesmen to sell this year's commission plan to the sales force. Because they always changed it every year to emphasize the things they wanted to push and deemphasize the things they didn't want to push or would sell themselves, they felt. And they had very good salesmen in sales management to sell this— the opportunities in the new plan to the sales force. So it gave them an opportunity to fire up the sales force again at least once a year. And if you don't change this commission plan, or don't have one, you have to try and invent other opportunities.

Kossow: So then you ended up in Computer Special Systems after that?

Russell: Yeah. One of the things that I ended up doing was configuring special systems. And at one point they decided to put selling standard systems in one group and selling special systems with one-off configurations and special peripherals in another group, and I ended in that group and ended up doing a lot of figuring and some amount of sketching out solutions for, you know, listening to customer problems and sketching out solutions. Oh, I guess it was before then, one of— this— because I worked on the remote printer thing I got also involved in the software. And the first version of software had a problem that it was written by a guy who was somewhere around the world's worse software designer, but unfortunately one of the world's best debuggers. And so he had debugged this software almost into operation. And he left, and I had inherited it. And it was in a race with one of the other guys in the group who was rewriting it reasonably from the ground up. Unfortunately he won the race, but I was only two weeks late, but it was a real slog because it was all PDP and assembly language. And it was a full PDP- 8 and it was full standard PDP-8 program, out of time and space. And to fix bugs, what the original perpetrator had done was say “oh, it fails under this condition, this condition, this condition. Okay, I'll recognize that and then get around the failing code.” So the code kind of grew, and ran out of space, of course. So a fair amount of the time what I would do is discover I didn't have enough space for the next patch that needed to be put in. So I'd run through and find all the flags that indicated the various horrible conditions that were no longer used because I had removed the problem, and eliminate the code that set and reset those flags, then run a cross-reference again and discover some more code that that eliminated. And so I do this algorithmic simplification for about a week and then I'd have enough space in most of the pages so I could do some more patching.

Kossow: The standard PDP-8 programming, where it doesn't fit, and then you squish the subroutines until it fits. And then you repeat.

Russell: Repeat until done, yes. It was educational but not particularly rewarding. And as I say, it took just as long for another guy to rewrite the code from scratch with a little discipline and get it working as it did to fix the broken code. And, of course, the final result was infinitely better because there was still some space to add features.

Kossow: But somebody in management give this guy the task of doing it.

Russell: Yeah. Ah, yes, there was COBOL. One of the things that was going on was Digital was writing COBOL for the PDP-10, or was getting a COBOL for the PDP-10. I don't remember if it was all in-house or external. And so I tried using it. I did a TMRC timetable in COBOL. Well, I'd never written COBOL, so I was sort of using the manual and what I knew. And so I ended up using multiple subscripts on an array. I forget what else, but basically what I was doing was writing FORTRAN in COBOL. Well, apparently nobody had tested those things, and so, in particular, the double subscripted array just was just plain a bug. It just started out not working, so I filed a software performance report. Funny how they always report bad performance and never— very seldom saw one with good performance. At any rate that got fixed and the program eventually got working. And it turned out one of the things that we needed was indexed sequential access. This was an IBM buzz word that was around and it's basically an indexed file. And it turns out to be a— it was very useful for random access files because you could look them up on the main index and you could get to essentially any size file that you could hold in about three disk accesses, which is wonderful compared with doing it sequentially or almost anything else you can do. And in fact, it's about as good as you can do. And so I ended up writing some ISAM routines for COBOL. And I hadn't particularly looked at other— the IBM implementations were sufficiently surrounded by jargon that it

was hard to penetrate what was going on. So I sort of winged it and ended up with essentially the right solution. And that worked and sold a system, I believe. And unfortunately there was one bug which I never got fixed, which was if you deleted— if a block got completely deleted and went to zero, somehow it— the pointers got confused and the software crashed. Didn't damage the file but it did crash and you had to restart it. But that was interesting, and the solution was very neat and very nice. I used something like the Stanford trick where in the block there was some metadata hidden up at the top of a block. But at least you didn't have to copy the block forward, you just split— when a block filled up you just split the block into two new blocks. And then one write of the index, change the index from pointing from the old one to the new one. So if you had atomic writes, which the hardware usually did, the file would be in good order no matter what.

Kossow: So I guess this is right around the time when the Magnavox lawsuit happened and you had to dig up all the old Spacewar! code?

Russell: Yeah. The time Magnavox lawsuit was happening, I don't remember exactly what the timing on that was but I had to— they wanted copies of Spacewar!, and so I dredged up my copes of Spacewar!. I made some copies for myself and gave them the originals which had the date of my writing on them, and which eventually I think came into the computer history collection, and did a deposition, which didn't go very well. That was about the most reward I ever got for Spacewar! was I got a free lunches from— free dinners from the lawyers. I guess I didn't mention that when Spacewar! was written there was— in principle we were not allowed to patent software and you couldn't copyright it. So there was basically no protection for programs at all. Later on that got changed, but that was the situation with Spacewar!. The only choice you had was never revealing the sources or making them open.

Kossow: Which was hard to do in a university.

Russell: Yes.

Kossow: How long did you end up staying at DEC?

Russell: Eight or nine years. After Special Systems, I went off on a consulting contract to New Zealand which was fun for me, but worked out really poorly. And so I ended up getting shunted off into running the message switching system, the internal Teletype message switching system and herding that for a while, while a new one was being written.

Kossow: So it was like an internal TWX system?

Russell: Yeah. And then eventually I got disgusted with that and tried to fit in another couple of places and that didn't work. So I got laid off and after a while started working for Chase Interactive Services, which was a interactive money transfer subsidiary of Chase Manhattan Bank, which was located in Waltham and was doing money transfer on IBM, big IBM 360s. And I did software on that in COBOL, and also ended up dealing with a worldwide communication system. One of the disadvantages of being in Boston and having the bosses in New York was you've got to have meetings in New York. And Boston wasn't far enough away so as you could do it overnight. So you had to get up at some God-awful hour in the morning, get to the airport, take the shuttle and get into New York about 10:00 and have your— have a day full of meetings and then go back, which made a long and ugly day. I learned a certain amount about expectation control, I guess, from that. There were two pieces to the system. One was a domestic money transfer system where people would deposit— typically branches, subsidiaries, licensees would deposit money in— at various remote locations into some kind of bank account and would call in what they had deposited. And Chase would accumulate it all and make it available as a usable balance for the customer. And so that involved a lot of phone calls of people calling in. And they would typically just call in the dollar— report an account number and a dollar amount. And we had a phone center that took those calls and typed them in on various types of terminals. And the thing I learned from that was that even trained and skilled operators who did that for a living still had a 1% error rate or so. And that's really the best you can hope for, for any sort of keying operation or most any sort of thing that people do. It was constrained, they got plenty of practice. They were reasonably motivated. They weren't dumb. And that's the best you can do. And you still have a lot of people who think they don't make mistakes, and they do. They make at last one percent. And if they're really bad they make 15%. And that's what you have to deal with in designing a human interface.

Kossow: So there had to be all this audit stuff to reconcile the errors?

Russell: Yeah, banks have been running with people for centuries. So the controlling that and dealing with fixing it up was a well-understood and routine operation. The worldwide money transfer system had another problem. It was a state of the art system with PCs, out in the far corners of the world, and it handled big money transfers. Unfortunately the software on both our end and the PC end was not perfectly reliable, it turned out. And the standard sort of problem would be you'd get an operations vice president from Tokyo, or London calling in and saying, "We've got to close the books in 15 minutes and we can't close the books. You've got to do something." Now, unfortunately, closing the books in London, New York, and Tokyo and Sidney is nicely distributed around the clock. So these calls would come in at 6:00 in the morning or midnight. And so it was an unpleasant support nightmare which I started out handling with three or four other people and eventually it got down to two. And when I announced I was leaving, the other person stopped speaking to me and never spoke to me again.

Kossow: Did you just end up digging through the database trying to find out…

Russell: Well, that was what I learned out about expectation control. It turned out the right thing to do was to do a very quick look or a quiz of the reporter to find out about what the problem looked like and then call my boss, so my boss got the word before it came down— before the shit started coming down from above. And so it ended up spending about half-time telling my management what was going on and the other half of the time actually working the problem. And sometimes the problem wasn't soluble, and there were times when we were told we had to close the books in 15 minutes and the books didn't get closed.

Kossow: So they can't close them till they balance?

Russell: Yeah. And if the system won't give them any numbers they don't even have the raw material to balance with.

Kossow: So this is the early '80s then, so pretty much everything is 370s so you're not working with batch anymore?

Russell: No, this was CP/CMS. Just sit at a terminal and correct the COBOL and then tell it to try it, and look to see what happened.

Kossow: So then at some point you moved back to the West Coast? Well, I guess so because you're out here now.

Russell: Yes. <laughs> Tom Zito was a…

Kossow: Well, he's ex-Atari.

Russell: He was promoting the idea of doing video games on VCR— on TV sets. He was starting an operation as part of Nolan Bushnell's Atari. Actually I forget, only very briefly I believe we were part of Atari.

Kossow: So they were still in Borregas in Sunnyvale?

Russell: We started out in the— where was it? Maybe it was always Axilon. There's…

Kossow: That's where Androbot and…

Russell: Was it currently— well it's not clear. There's this rusty building on— just off Lawrence [ph?] by 237.

Kossow: The triangle building?

Russell: No, it's not triangle, it's square. But the COR-TEN self-protecting steel siding, so it's a dark rust color, and that's where we started out. The building's still there. The enterprises have changed at last once.

Kossow: I was thinking of 280. The triangle building's 280. Yeah, 237.

Russell: Like the Mill, buildings stay through an awful lot of enterprises.

Kossow: Yeah, it's like that whole corner down 237 in Sunnyvale where CDC used to have all their software operations. It's down in there.

Russell: Anyway, that was the start…

Kossow: How did you end up getting linked up with Zito and the people on the West Coast?

Russell: Zito knew of me because of Spacewar!, and thought that since he was in the game business I would be an asset. I guess I was, but, you know, the whole enterprise didn't work out perfectly. But the idea was to record special material on a VCR tape and play the VCR, use your VCR, to play into a special box which would have game controllers on it and allow you to play a game on your TV set with TV-quality pictures. Now at the time you couldn't afford to synthesize them. There wasn't enough computing around to do that.

Kossow: And it would have been cheaper than a video disk.

Russell: There was electronics for doing frame storing. So with a frame store that held a couple of frames and a control box, you could selectively pick frames off the interlaced video on— from the VCR and so you could switch around. We developed the electronics. And the way it finally worked out was you could have four live video streams and periodic other updates. So what you could do is do a mass design which had the game control stuff on it and you could pick one of four video streams to show live at almost video quality in the picture window that was let through by the mask. And so you could do various sorts of games. And the two kinds of games that we ended up developing were either sports games like football where you got to choose what move to make and then it played out, or a surveillance camera sort of thing. There was a title, Night Trap, which got transmogrified through a couple of different iterations but started out in the video version. The idea was that you had a surveillance camera that looked at a bunch of places in a house. And the house was being used for a weekend party by a bunch of teenagers and was invaded by some evil monsters called Auger, which look like human beings in black leather. Look amazingly like human beings in black leather. And the idea was that the house had traps, trap doors in it. And you looked around and figured where the monsters were coming in. And if you saw one, if you hit the trap door at the right time it would disappear and you'd get a score. And if you didn't get them all then the teenagers were carried off by the monsters and you lost. But if you did get them all then you'd save them and so on.

Kossow: What year was this?

Russell: Not quite sure.

Kossow: Mid-'80s?

Russell: Yeah. So that wandered on through development in a couple of demos, and it got sold to Hasbro. So it was Hasbro Electronics for awhile. And we got that developed to the point where it was a go/no-go production decision, and Hasbro decided no-go, probably correctly. And so that folded up and I went off and worked for— did various sorts of consulting and ended up working for X-Ray Instrumentation Associates for a while doing gadgetry for x-ray work. And then it revived itself as digital pictures which was taking the same video material and more, and fixing it so it would play on PCs and Macs. I think that was around '85, '86. It was just when we were going from Windows— from DOS to Windows, I believe. No, I think it was going— yeah. And so I ended up taking the code that had— the C code that had worked on the Macintosh and bashing that into submission working on a PC for Night Trap. And that just barely got out and got published. And we did not have a successful Christmas season, and that folded up. Then I was looking around and started working for Nohau who made microprocessor emulators. And what I was working on there was software which was interacting debugging for C programs. So this is back to making DDT. But the machine was considerably more complicated and it was more C stuff, and so it was considerably more complicated. And the disassembler actually was worse than the PDP-1 disassembler, but I never— it was never the worse problem that we had to deal with so I never ended up…

Kossow: So it was for different microprocessor targets?

Russell: Yes, 8051s was our staple business and it's changed hands, but that business is still sort of alive. And I was working on Motorola 68000s and 6800s mostly.

Kossow: This is Tape No. 5, the oral history of Steve Russell. So you had switched then from mainframe work, through games, into tools and debuggers and things like that. So we're kind of into the early '90s.

Russell: Yes.

Kossow: So you've been working on tools since then?

Russell: Yes. Tools and, you know, board and microprocessors, board support type, but debugging and board support type tools.

Kossow: Like embedded systems?

Russell: Yes.

Kossow: And you were, I'm trying to remember, the company that you're with.

Russell: Nohau.

Kossow: Nohau. Oh, those are the little, white boxes that?

Russell: Yes.

Kossow: Ah, okay.

Russell: The original scheme was you have an 8051 on a board, and a tentacle so that you can plug it into an 8051 socket. And you can run the 8051 programs in the one in the box at full 8051, full, old 8051 speed, and operate your board as if the processor, as if it was plugged into the board, but you get debugging. You get visibility on all the memory references and a reasonable debugger, so that you could do source-level debugging.

Kossow: So it had like overlay RAM and then address traps and the usual sorts of things that in-circuit emulators have.

Russell: And that whole business kept getting transmogrified as the chips got faster and faster and denser and denser. The original scheme played a lot of games which depended on the original 8051 architecture. And as it evolved, and other people started doing 8051's, that kept having to get tinkered to deal with the latest hardware. And they also did ones for the Motorola 6800 family. There was a 8-bit 6809 derivative family that was system on the chip, and 68000 derivatives that were systems on the chip. And there the interface was considerably different, because they had different memory interface, and they had background debug mode, which was a not many wire debug interface to the processor.

Kossow: So these were the CPU32 [Motorola CPU 32 processor family] things. Little ten-pin connectors.

Russell: Those got used a lot. The Motorola systems got used a lot in the automotive business for ignition control, engine control, and miscellaneous function control. So they could afford relatively luxurious debugging facilities, although they eventually got over it.

Kossow: And so did you end up working on the firmware that was in the boxes, or the tools that ran on the PC's that controlled the boxes?

Russell: Both. It turned out I was primarily working on the Motorola or Freescale systems, and there you didn't have to do much in the box, but you had the single wire, or not many wire debugging interface, which is basically a serial half duplex interface to talk to the memory and do run control on the processor.

Kossow: So were they bought out by Arium?

Russell: No. Nohau went bankrupt a couple of years ago, and the business got bought up by ICE Tech [ICE Technology], and ICE Tech is still more or less a business. They aren't doing much software development, and I don't believe they're doing much new design, but they're selling the old products and supporting them. And there's still quite a bit of 8051 business apparently, and there's some Motorola business still, too.

Kossow: Did you ever work with ARM at all?

Russell: Only very, very peripherally. Nohau did support ARM, and occasionally I had to help with it, but I didn't have to get into all the details of ARM.

Kossow: Okay. So when did you get involved with the Museum? Were you involved much at all with the Museum in Boston?

Russell: I was involved in the Museum in Boston only in coming to the Spacewar!, the PDP-1 revivals, or one of them for 15 through 20th, or something, anniversary of Spacewar!. That must have been when I was working for DEC. There's a picture from that on the wall somewhere. And then I was working. Let's see. When I got out here at one point I got vaguely involved in the Computer History Museum in that I unloaded all my back issues of Datamation on them. Not a terribly unique contribution, but at any rate it cleared out my garage a little. And then I kept an occasional contact. They had a Spacewar! revival at Moffett where Bill Pitts had a computer, had Galaxy working. So, you know, they knew more or less where I was. And so when the PDP-1 restoration project got started, they got in contact with me, and I sort of said, "Yeah, yeah, do it." And then for the first, I think, two years, mostly what I did was monitor the email, and when they were saying, oh, my God, the display doesn't work, or the paper tape reader doesn't work, I'd say, "oh, yeah, they used to fail."

Kossow: And you've been getting more and more involved ever since.

Russell: Yes. Well, now I get a new audience every couple of weeks, so I can tell the same old stories.

Kossow: Bill Pitts.. that just reminded me. Did they have much contact with you while that was all going on? Did they ever talk to you about Spacewar! back then?

Russell: Back when?

Kossow: When they were working on Galaxy Game?

Russell: No. Bill Pitts, you know, he was hanging around the AI project when I was working there, and he certainly knew what Spacewar! was. And shortly after I left, he got the idea that he could build a multiuser Space War PDP-11 and collect quarters, and he did. And he and Ted Panofsky did a fair amount of work restoring that system. And he has grumbled at me several times since that the Museum doesn't keep it working.

Kossow: Yeah. Do you have any other thoughts?

Russell: Well, there is a pitch for a pet project or two I'd like to do. One of the things which I believe I can still do. We don't have working Flexowriters, and I can't demonstrate it. But I believe I can show how, in the thrilling days of yesteryear, how we used to edit programs on a Flexowriter and give some impression of how slow it was but how it was still possible to get work done. And I think a mercifully short video can be made of that, and I think we can also do something that's longer and is a useful full explanation. But I think somebody, probably me, needs to do some writing. Because my impression is that something like that, the mercifully short demonstration especially isn't going to fly if it isn't scripted. Not that I'm good at following scripts, but writing the script is a good exercise and it allows you to time it. And if you rephrase it on the fly, then it usually doesn't upset the timing too much. Actually, I think it would also be useful to get a similar thing for a keypunch, as there some of the details of card drifting and stuff that are important to getting things done and make it a little less painful. But actually I was thinking that one of the things— Remember I mentioned with Lisp how, if we had segregated the storage, it would have been a lot easier to debug, and there would have been a lot fewer garbage collector problems? That is something which nowadays with good editors, and programmable editors, and easy copy and paste, I wouldn't hesitate to think about if I had a program like Lisp stated without the garbage collector, I wouldn't hesitate about going back and segregating all the storage and doing those changes. But in the days of cards, when doing this to a card deck involved a great deal, no checking and a great deal of grief, it was just sort of something that was just too horrible, and it's now something which I would easily consider doing.

Kossow: Yeah. Just the state of tools that have. People complain that the tools really haven't evolved very much, but, right. Yeah.

Russell: <laughs> Well, one of the noted but forgotten, but unread pieces of literature is this Mythical Man Month. At Juniper, where I'm working now, we're dealing with a version of FreeBSD and applications, which is huge. At last report there were something, there were claimed to be 6,000 software engineers

working on it. And they're complaining about we aren't getting features done on time. It takes too long to do a compilation. You know, all of the tools are just too slow.

Kossow: Maybe the code is just too big.

Russell: Yeah. But the code is probably at least one, and probably two orders of magnitude bigger pile of code than the system 360, which provoked Mythical Man Month.

Kossow: Right. And in 2008 the size of systems that we're trying to deal with are just so much bigger than was being done in the '60s. Right?

Russell: Yeah. And one of the other things is almost none of those software engineers are writing— are dealing with brand new designs. They are dealing with an extension or a modification of a current design.

Kossow: Or they're implementing something that's a standard.

Russell: Yeah.

Kossow: That you have to deal with what is the—

Russell: Or taking the standard thing and it's got a new. Well, okay, this worked on last year's hardware, but now we have this year's hardware and the interface is different. And the system starts out on a dual-core control system, and that actually deals with a third of maybe four to 32 separate subcontrol systems that actually shovel packets. And those are now being implemented on N-Core MIPS systems where N is greater or equal eight.

Kossow: It's a lot of processors.

Russell: Yeah.

Kossow: So then you have all the synchronization nightmares.

Russell: Yeah. Well, there's a sort of old curmudgeon lunch group that periodically marvels at the state of things. And their sort of consensus is there are probably still a bunch of one-liners in the operating system. It's just that nobody particularly excites them. And probably if the load were radically different there'd be a whole bunch of new bugs that show up. But because the load isn't radically different, and the environment is reasonably settled and reasonably stable, it's possible to produce what looks like very reliable software, which is what is in practice very reliable software.

Kossow: You just never tickle the bugs.

Russell: Yeah. But we think they're there. It's okay since we know they're there. But it's still, I don't know the counts, but I think FreeBSD is probably spectacularly larger than System 360. And I know that what we distribute is spectacularly larger than FreeBSD, 'cause there's a whole pile of high performance applications in there. And so it's amazing. And we managed to make it work, but it's easy to prophesize gloom and doom.

Kossow: So would it have been better if it would have been implemented in Lisp instead of C or C++ or whatever it's being implemented in?

Russell: C damn it. C++ has been dragged in with kicking and screaming. But most of the code is still being implemented in C, and there is no— Well, I guess some of that you can blame on the free software movement, too, which likes C because it's more portable than C++, or five years ago, it was more portable than C++. One of the things that I did do when I was working at Nohau was every now and then when I had to do major surgery on a module, I would spend the extra two hours or so it took to make it compile in C without errors and then compile in C++ without errors. And when I did that, then the C, the somewhat better type checking in C++ would find my errors better. And even though it was still C, it was still written as C, we were was still ahead compiling it in C++. But Juniper isn't to that point yet.

Kossow: Now, it's the issue of having to turn products and just push out the next product after this one is done.

Russell: And, well, there are some pieces of discipline that Juniper has fairly well. They do insist on reviews before check in. And a lot of the reviews are thoughtful reviews. There are some disparaged groups that seem to do a lot of rubber stamp reviews. However, when they integrate with the full system, they seem to have a lot more problems. No, Lisp would not be a good language to implement something like a high performance router like Juniper is doing. There's a basic problem with garbage collection. If you do it simply, it causes everything to stop when it happens. And if you do something to avoid that, the overhead on the garbage collection becomes a lot more, and you still end up writing code with the illusion that free storage is infinite. And there's no way to guarantee— Free storage is not infinite. And reviewing code to establish or prove that it uses a bounded amount of storage, is really, really hard, and probably in a complicated system, a system with anywhere near that many lines, you don't stand a chance. And so it's questionable whether you should even start on using Lisp for something like that.

Kossow: What I was thinking was just a higher level language other than C.

Russell: I think there are a bunch of places where C++ or Modula 2 or 3 or, you know, something like that, which allows you to have objects, and encourages some discipline, would be a better way to do things from scratch but, you know, how you would get there from here is a little hard to say. One of the things which— if you can constrain the set of objects available, the types of objects available, to the class program so that you can say these system routines can only use these objects. The device drivers can only use these kinds of objects, and you can handle all— You could arrange to handle all of the interprocessor communication or inter-thread communication through a constrained set of objects where you have to use the high priority version if you're running a high priority thread, and you have to use the low priority version if you're running a low priority thread. I think you could build a structure that is a lot more—a lot better at gracefully dealing with errors and a lot better at not encouraging stupid programming errors. But I ain't see one, and I'm not sure I'm prepared to design one.

Kossow: So there it is, the state of programming in 2008.

Russell: The state of one corner of programming. These are embedded systems, by the way.

Kossow: Right, where things break. Your car stops working or, your packets don't get routed.

Russell: Or the Internet gets stolen.

Kossow: We haven't talked about security at all. Oh, well, thank you very much for this marathon session.

Russell: You're welcome

Immunology, virology

Albert Bruce Sabin (/ˈ seɪbɪn/ *SAY-bin*; August 26, 1906 – March 3, 1993) was a Polish-American medical researcher, best known for developing the oral polio vaccine, which has played a key role in nearly eradicating the disease. In 1969–72, he served as the President of the Weizmann Institute of Science in Israel.

Biography[edit]

Abram Saperstejn (later Albert Sabin) was born in Białystok, Russian Empire (before and since 1918 in Poland), to Polish-Jewish parents, Jacob Saperstejn and Tillie Krugman.[1] In 1921,[2] he emigrated with his family on the SS *Lapland* which sailed from Antwerp, Belgium, to the Port of New York. In 1930, he became a naturalized citizen of the United States and changed his name to Sabin, as well as assuming the middle name Bruce. He graduated from high school in Paterson, New Jersey.[3]

Sabin began university in a dentistry program, but was interested in virology and changed majors. He received a bachelor's degree in science in 1928 and a medical degree in 1931 from New York University.[3][4]

In 1983, Sabin developed calcification of the cervical spine, which caused paralysis and intense pain.[5][6] Sabin revealed in a television interview that the experience had made him decide to spend the rest of his life working on alleviating pain.[7] This condition was successfully treated by surgery conducted at Johns Hopkins Hospital in 1992 when Sabin was 86. A year later, Sabin died in Washington, D.C., from heart failure.

Medical career[edit]

Sabin trained in internal medicine, pathology, and surgery at Bellevue Hospital in New York City from 1931 to 1933. In 1934, he conducted research at The Lister Institute for Preventive Medicine in England, then joined the Rockefeller Institute for Medical Research (now Rockefeller University). During this time, he developed an intense interest in research, especially in the area of infectious diseases.

In 1939, he moved to Cincinnati Children's Hospital in Cincinnati, Ohio. During World War II, he was a lieutenant colonel in the U.S. Army Medical Corps and helped develop a vaccine against Japanese encephalitis. Maintaining his association with Children's Hospital, by 1946, he had also become the head of Pediatric Research at the University of Cincinnati. At Cincinnati's Children's Hospital, Sabin supervised the fellowship of Robert M. Chanock, whom he called his "star scientific son."[8]

Sabin went on a fact-finding trip to Cuba in 1967 to discuss with Cuban officials the possibility of establishing a collaborative relationship between the United States and Cuba through their respective national academies of sciences, in spite of the fact that the two countries did not have formal diplomatic ties.[9]

In 1969–72, he lived in Israel, serving as President of Weizmann Institute of Science in Rehovot. After his return to the United States, he worked (1974–82) as a research professor at the Medical University of South Carolina. He later moved to Washington, D.C. area, where he was a resident scholar at the John E. Fogarty International Center on the NIH campus in Bethesda, Maryland.

Polio research[edit]

Sabin (right) with Robert C. Gallo, M.D., *circa* 1985

With the menace of polio growing, Sabin and other researchers, most notably Jonas Salk in Pittsburgh and Hilary Koprowski and H. R. Cox in New York City and Philadelphia, sought a vaccine to prevent or mitigate the illness. This was complicated because there were multiple strains of the disease. In 1951, the National Foundation for Infantile Paralysis's typing program confirmed the existence of three main serotypes of poliovirus, since known as type 1, type 2, and type 3.[10][11][3]

Salk developed an inactivated poliovirus vaccine (IPV), a "dead" vaccine given by injection, which was released for use in 1955.[12][13] It was effective in preventing most of the complications of polio, but did not prevent the initial intestinal infection.[13]

By carrying out autopsies of polio victims, Sabin was able to demonstrate that the poliovirus multiplied and attacked the intestines before it moved to the central nervous system. This also suggested that polio virus could be grown in other tissues besides embryonic brain tissue, leading to easier and cheaper methods of vaccine development.[3][10] John Enders, Thomas Huckle Weller, and Frederick Robbins would successfully grow poliovirus in laboratory cultures of non-nerve tissue in 1949, an achievement that earned them the 1954 Nobel Prize in Physiology or Medicine.[3]

Sabin developed an oral vaccine based on mutant strains of polio virus that seemed to stimulate antibody production but not to cause paralysis. Recipients of

Sabin developed an oral vaccine based on mutant strains of polio virus that seemed to stimulate antibody production but not to cause paralysis. Recipients of his live attenuated oral vaccine included himself, family, and colleagues. Sabin's first clinical trials were carried out at the Chillicothe Ohio Reformatory in late 1954. From 1956–1960, he worked with Russian colleagues to perfect the oral vaccine and prove its extraordinary effectiveness and safety. The Sabin vaccine worked in the intestines to block the poliovirus from entering the bloodstream.[3]

Between 1955 and 1961, the oral vaccine was tested on at least 100 million people in the USSR, parts of Eastern Europe, Singapore, Mexico, and the Netherlands. The first industrial production and mass use of oral poliovirus vaccine (OPV) from Sabin strains was organized by Soviet scientist Mikhail Chumakov.[14][15] This provided the critical impetus for allowing large-scale clinical trials of OPV in the United States in April 1960 on 180,000 Cincinnati school children. The mass immunization techniques that Sabin pioneered with his associates effectively eradicated polio in Cincinnati. Against considerable opposition from the March of Dimes Foundation, which supported use of Salk's relatively effective killed vaccine, Sabin prevailed on the Public Health Service to license his three strains of vaccine. While the PHS stalled, the USSR sent millions of doses of the oral vaccine to places with polio epidemics, such as Japan, and reaped the humanitarian benefit.[10] Indeed, it was not clear to many that the vaccine was an American one, financed by U.S. dollars, as it was not widely available to ordinary Americans.[*citation needed*]

Sabin's first oral poliovirus vaccine (OPV), for use against type 1 polioviruses, was licensed in the US in 1961. His vaccines for type 2 and type 3 polioviruses were licensed in 1962. At first, the monovalent poliovirus vaccines were administered together by being put on a sugar cube. In 1964, a single trivalent OPV containing all three viral serotypes was approved.[13][10] Sabin's oral vaccine was easier to give than the earlier vaccine developed by Salk in 1954, and its effects lasted longer. The Sabin vaccine became the predominant method of vaccination against polio in the United States for the next three decades. It broke the chain of transmission of the virus and allowed for the possibility that polio might one day be eradicated.[3][10]

Sabin also developed vaccines against other viral diseases, including encephalitis and dengue. In addition, he investigated possible links between viruses and some forms of cancer.

Philanthropy[edit]

Sabin refused to patent his vaccine, waiving every commercial exploitation by pharmaceutical industries, so that the low price would guarantee a more extensive spread of the treatment. From the development of his vaccine Sabin did not gain a penny, and continued to live on his salary as a professor. The Sabin Vaccine Institute was founded in 1993 to continue the work of developing and promoting vaccines. To commemorate Sabin's pioneering work, the institute annually awards the Albert B. Sabin Gold Medal in recognition of work in the field of vaccinology or a complementary field.

Awards and recognition[edit]

Leaders in the effort against polio were honored at the opening of the Polio Hall of Fame on January 2, 1958. From left: Thomas M. Rivers, Charles Armstrong, John R. Paul, Thomas Francis Jr., Albert Sabin, Joseph L. Melnick, Isabel Morgan, Howard A. Howe, David Bodian, Jonas Salk, Eleanor Roosevelt and Basil O'Connor.[16]

The CARE/Crawley Building houses the University of Cincinnati College of Medicine.

- For the trivalent oral vaccine consisting of attenuated strains of all three types of the poliovirus, the President of the Supreme Soviet of the USSR awarded the highest civilian honour, the medal of the Order of Friendship Among Peoples (1986).[17][18][19]
- Election to the Polio Hall of Fame, which was dedicated in Warm Springs, Georgia, on January 2, 1958
- Howard Taylor Ricketts Prize (1959)
- Robert Koch Prize (1962)
- Feltrinelli Prize (1964)
- Lasker-DeBakey Clinical Medical Research Award (1965)
- National Medal of Science (1970) [20]
- Medal of Liberty (1986)
- Presidential Medal of Freedom (1986)
- The Cincinnati Convention Center was named after Sabin from 1985 to 2006.[21]
- In 1999, Cincinnati Children's Hospital Medical Center named its new education and conference center for Sabin.
- The street that runs between the University of Cincinnati College of Medicine and Cincinnati Children's Hospital Medical Center was renamed Albert Sabin Way on April 28, 2000.[22]
- On March 6, 2006, the US Postal Service issued an 87-cent postage stamp bearing his image, in its Distinguished Americans series.[23]
- In early 2010, Sabin was proposed by the Ohio Historical Society as a finalist in a statewide vote for inclusion in Statuary Hall at the United States Capitol.
- In 2012, Albert Sabin was named a "Great Ohioan" by the Capitol Square Foundation.[24]

Side 1; Page 1

Q . trying to pick up, as it were, the strings of your laboratory after World War II. Now, last time we left you, you were working in the Rockefeller Institute Laboratories in Princeton. You had worked on dengue; you had worked on Japanese Encephalitis. You had made trips to Panama and to Japan. How did you get back to Cincinnati, and what was the nature of your operations when you returned to Cincinnati.

A Actually, I returned to Cincinnati before I went to Panama early in 1946 and before I went to Japan, China, Korea in 1946 because at that fime I already ~ a civilian. My laboratory in Cincinnati had to be completely reconstituted because the people who were my co-workers at the Rockefeller Institute at Princeton except one who was carried over--they all were different people. One of the people that I brought with me, back with me to Cincinnati to provide some continuity was Dr. Walter Schlesinger who . originally came to me because he had worked with Dr. Olitsky at the Rockefeller Institute and it was a sort of continuity and when he was commissioned an officer, he worked with me at the Rockefeller Institute at Princeton. However, he was not with me on Okinawa, you see. But, when we started back up the laboratory in Cincinnati we had to have some new people. One of the people who came to work with me was a man who had been a resident in pediatrics at the Children's Hospital: Dr. Richard Blumberg who subsequently became head of the department of pediatrics at Emery University, in Atlanta. And ~~ had to get a new staff. The program was in part a continuation of unanswered questions that were left over from the research during the War period, and that concerned problems in dengue. And that I continued with Dr. Schles~inger. He also accompanied me then to Japan because when I had to organize a new unit for work on encephalitis in Japan he carne with me. Subsequently the broad outlines were to continue in part with the problems in various outlying areas of the world, particularly the Far East in which I had become involved during World War II. But, to start to return to the study--systematic study of poliomyelitis which was interrupted actually in 1943 when I went into uniform and left the laboratory. But there were certain other things that weEe carried over. And they were problems--I might call them problems of opportunity that you don't plan on, but which arise in the course of the search for understanding in other areas. One of these problems that remained in my mind actually began at the Rockefeller Institute of Princeton with a very peculiar observation that the yellow fever vaccine that I had to use in my studies on human volunteers in the Trenton State Prison for its possible affect dn dengue infection of New Guinea and other places--that an extraordinary event occurred that had a bearing on an old problem of the genetic constitution of the host in relation to its response to viruses. I wonder if I may begin on that now.

Q Oh, please. Why don't you begin on that now. We can come back to other things later.

A Because this provides a transition from the work at the Rockefeller Institute at Princeton. It was a question left hanging. It was a basic question not directly virus didn't kill the mice quite the same way. In some, related to any specific problem that had to be solved. To any mission-oriented problem. There had been observations in previous years with using certain strains, with certain strains of mice that W were used for work in yellow fever that had indicated

had been observations in previous years with using certain strains, with certain strains of mice that W were used for work in yellow fever that had indicated that when you used different strains of mice, the yellow fever let's say 100% would die after a certain inoculation, and mice were used to standardize the potency of yellow fever vaccine for use in man, was standardized by determining the killing power in mice--intracerebral virulence in mice. But there was never a clean-cut thing of this group of mice is 100% resistant. This group is 100% susceptible. There were always different strains of mice in which there were variations in percentages. But something happened during my work on dengue at the Rockefeller Institute at Princeton which was a departure for something from which I got a great deal of joy and which gave us a real insight into at least one aspect of genetic resistance to infection with certain viruses. I obtained some yellow fever vaccine from Dr. Max Theiler from the Rockefeller Foundation where they had been making the vaccine in New York for use on human volunteers. I inoculated the human volunteers at the New Jersey State" Prison with this vaccine. Subsequently they were to be inoculated at different times with dengue virus to see or rather to get an understanding of what may happen in the

~ . field. ~ soldlers who had been vaccinated against yellow

fever, are then taken into an area in which dengue is

prevalent. There were reasons for doing this.

But, as is my custom, right after I finished

inoculating the human volunteers, the prisoners, with--.

I hope this prisoners is not misunderstood. They were real

volunteers. Civilians with them. I took the vial back to

the Princeton Laboratory to do a titration to make sure that

the material that just went into the people really had full

potency--despite the fact that Max Theiler told me it ~

alright--to double check. I have to do it on myself to make

sure that that particular ampule that I used didn't have

something wrong with it. That was my way of working, always.

And, I did it on mice that had been inbred for more than

25 years at the Rockefeller Institute at Princeton, and 10

and behold, it had no potency. Well, Ehe shock was great.

Because I said, here, I spoiled my experiment. I called up

Max Theiler to tell him this, and I said, "Max, did you test ,,~\,,*

out what ampules of this before you sent it to me?" He said

"You know I wouldn't send you inactive stuff. Of course I

did and it had full potency."

Well, certainly, I said, "The ampule that I used

certainly didn't have any potency here." So, we decided to

find out what was wrong, and I sent him back some of the

stuff that I still had for titration in New York. And he

sent me another ampule from the same lot for titration In

Princeton. And 10 and behold, in New York, full potency--

all the mice died after intracerebral inoculation with way

out, a high titer, and in Princeton again, another ampule,

it doesn't work. So, the suspicion arose that the inbreeding

of mice, even though they are all supposed to have come from

some stock years ago at the Rockefeller Institute in New York,

had brought~about some change in the mice. But at any rate,

when I then got some mice myself from the Rockefeller Institute

in New York, and the Rockefeller Institute at Princeton, and

did a simultaneousltest with the same stuff, beautiful, 100%

died with the New York mice--Swiss, white Swiss mice. 100%

survived. I said, "My God, what a wonderful opportunity to

Incidentally, I was highly gratified because he

do genetic experiments, crossing, find out what is the basis

of this resistence, how many genes determine it." But there

were too many other things to do. I had to go off to Japan,

and this was postponed. So when I returned to Cincinnati, I

,~

had a very nice young man, ~ Wallace, who had a masters'

degree, he came to work with me, so he went off on that.

subsequently went on to get his Ph.D. at Ohio State, then

he worked with Harvard and other places, and then quite

recently he, in recent years, became the first black professor

of microbiology in a southern university, at the University of

Kentucky at Louisville, University of Louisville.

To make a long story short, we became involved in

breeding in a typical Mendellian type of experiment.

Q Where did you get the mice? This sounds like a silly question. But, is there a special place where you could have gotten them?

A Well, there are breeders. The Princeton mice, which came to be called in my report, PRI--Princeton Institute mice-- I obtained from Princeton and then we bred them ourselves. And the Rockefeller Institute mice--white Swiss mice, again we got some from the Rockefeller Institute, and we bred them ourselves. So, for these genetic experiments, we didn't buy mice. We got them and we bred them.

Q The reason I asked that, is that I know there was one place which had specifically bred mice like the Jackson Laboratories.

A This was out. Because their mice would not have any of this inbred quality. The only mice where you could have 100% death and 100% survival were these Rockefeller Institute Swiss mice, and the Princeton's. And so, we got some of those mice because I had two floors of animal quarters, really. Animal quarters were an important facility at the Children's Hospital Research Foundation. So we bred those mice. There was no other way. Very carefully to make sure there was nothing else in the rooms and so on and so on. Then we did typical Mendellian type of experiments. We crossed we bred the Rockefeller Institute with the Princeton Rockefeller Institute mice, New York that is, with the Princeton Rockefeller Institute mice, got the first generation. You see, we would have to accumulate enough mice from different litters, and sure enough, without going into too much detail, which is contained in my publication, it worked out exactly as Mendell's it was a typical Mendellian ratio. The FI generation, the first cross between the New York and the Princeton mice were &00% resistent. And then there was a back cross, and then the second generation, the F2 came out very beautifully 25% fully susceptible, 25% fully resistent, others in between. At any rate, it was the first clean cut demonstration of the closest approximation to one gene determining susceptibility and resistence. But, it was also interesting that this gene was influencing something very special that applied to a certain group of viruses, like yellow fever and then we found that the related ones, dengue, the so-called arthropod, the D group. However, western equine, eastern equine encephalitis, other viruses that were pathogenic for mice were not affected by this gene at all. It was a gene that operated for something that was referable to one specific group of viruses. But then it was possible not only to show for the first time this beautiful genetic story for resistences and susceptibility, at least for one group of viruses and the specificity of it. You see, it was not some non-specific factor. But also, how it operated. What did that gene do? And it turned out that what that gene did was to determine what the level of viral mUltiplication should be in the mice so that in the mice that would go on and die, the susceptible ones, it would multiply up to a level of perhaps one hundred million mouse infectious doses per gram of brain whereas in the resistent ones, it still multiplied but only to a level of about 100 thousandths as much, you see--you see, ten to the two or ten to the three. And it could be shown that even when the resistent mice were inoculated with let's say, 1 to ten millionth dilution, something that would have one lethal dose for the susceptible strain, that still would multiply because you could then show it by the development of antibodies. So here was something that actually was--the gene was influencing the level of multiplication--and the level of multiplication influenced whether or not it shall be a lethal disease, a clinically apparent disease or an inapparent disease which nevertheless -V) gave rise to immune response~measured by antibody. **This was a very important observation, and of course, you still had to check to make sure that it was working at the cellular level, that it was not an affect that could be perhaps on the host which in general held down the level of multiplication to be sure for a specific group of viruses for some, not for others, and this was done in a very nice experiment that I did together with Alice Moore of the Sloan Kettering.** There was a transplant ~ tumor, called sarcoma 180 I don't know.

Q Alright.

A **Sarcoma 180, and it had been so differentiated that you could transplant it. It would grow in any mouse regardl~ss of its genetic origin. And, Russian Spring/Summer encephalitis was one of the viruses affected by this gene because it is in the b group of ~l ~ viruses. And Russian Spring/Summer encephalitis was shown by Alice Moore to have a great destructive effect on this tumor when it was transplanted into mice, because it grew in that tumor tb a very high level.** Perhaps ten to the 8, ten to the 9th per gram. The tumor was destroyed, but then the mice would die of the Russian Spring/Summer encephalitis virus. So we did the following We transplanted the Sarcoma l80--these are cells of an unknown--where, I mean, certainly they didn't come from the Princeton mice with this specific resistence. They were transplanted and allowed to grow in the resistent mice from the Princeton Institute. And then they were inoculated with Whereas in the brain it did not. So the mice survived, the Russian Spring/Summer encephalitis. And the multiplication within the tumor cells that were foreign to these mice and within the brain and other tissues was then determined quantitatively. And it turned out that in the transplanted sarcoma cells, it grew perfectly well to a very high level. tumor was destroyed, and i~ showed that it was not some general factor in the body of the mouse of this special genetic constitution that would influence with multiplication-- influence the multiplication of the virus anywhere in the body. This was a very striking experiment. Now, of course there was always in the back of my mind--polio never left me--no matter what neuratropic virus I worked on.

Q **You know, I have never run across Alice Moore's name before you just mentioned it.**

A **Well, Alice Moore had worked with Tommy Francis at the Rockefeller and then she got her Ph.D., and then she went to Sloan Kettering. She was one of the old soldiers so to speak.**

Q **Well, you know, I just hadn't run across the name.**

A Now, one of the interesting things, and this came out in the discussion, was that in any disease, infectious disease in which some people who are infected have a very mild, not even clinically recognizable disease, and others have a varying spectrum. The question always arises, what influence does the genetic constitut±on of the host have?

Q Yes.

A And naturally, I was alwa¥s interested in poliomyelitis which was the case par excellence in which a hundred people or a thousand people infected with the same virus maybe we don't know the dose exactly, but with the same virus during an outbreak and a small percentage become paralyzed, and others are not paralyzed. So the question was, to what extent does the genetic constitution of the host play the role. And sure enough, there were studies by M~cock on the families in the Tennessee hills that had been inbreeding that provided very clean evidence that there was some genetic factor that did play a role because in generations after generations there was an unusual incidence of the paralytic disease that couldn't be accounted for on where they lived. It was something heritable. Of course the other interesting factor--but let me carry this through later to polio which we will discuss more.

Q Yes.

A What I came to learn later, however, which now has I think a very important impact on my thinking about those problems is that the genetic variations, the genetic constitutions of different virus particles of the same virus ultimately have a much greater role to play and a role that you can control than the genetic constitution of the host. We are dealing with this in many different things. This is a big thing now in cancer. Genetic constitution plays some role in cancer. I am sure genetic constitution plays some role in other diseases, also. But, one must always keep in mind the probability that it is only a minor part of a more complex picture. The other interesting significance of this work. I am working now to the genetics of resistence to at least one group of viruses, is that it could explain what certain things, for example, why yellow fever in Africa, in the native population was a relatively mild disease whereas newcomers, foreigners, strangers coming in there would die like flies. Or, when it was transported to the Western hemisphere, killing epidemics. I think that this data provides an explanation that probably over eons of years in which y~llow fever must have existed in Africa together with the population that it killed off the susceptible portion of the population and left a population by this form of selection with genes that had the capacity to limit the multiplication of the yellow fever virus, that they were populations of different genetic constitutions. Wel~, there are similar aspects in other viruses, I am sure, but there was never the opportunity that was provided by shear chance by anything as serendipity--this is serendipity--of having 100% resistence, 100% susceptibility. Leslie Webster approached this problem in studying resistence and susceptibility with some of the different strains that he bred out from among the Rockefeller Institute Swiss mice. But there were differences, but there was never this clean-cut thing--at least for viruses. He had some for bacteria. So, this was an interesting side activity in which we spent a lot of time--John Wallace was a very excellent technical associate, highly reliable as his subsequent career proved, and I had gotten a great deal of gratification out of working this out because to be quite frank, I had to go back and study, refresh my memory, and study anew the basic principles of genetics, and I used to be in frequent conference with Dr. Lynch at the Rockefeller Institute who was the geneticist--Rockefeller Institute in New York--to check the data, and it was an interesting period.

Q And this is just a chance observation.

A During the work, the specific work on the influence of yellow fever vaccination of our troops, against the diseas~ to which they were exposed, like dengue, and then this then was followed up in the period after I returned to Cincinnati, made my special effort, and it took a number of years because it takes a number of years to do all this breeding, you see, and to collect enough mumbers. But it was an interesting thing.

Q Now, your unit in Cincinnati, Dr. Sabin, it was an autonomous unit, wasn't it.

A Well it was autonomous to the extent that I had a part of the facilities of the research foundation which with its own endowment, was nevertheless, a part of the University of Cincinnati. I had my--I had a floor myself, I had--actually kinds of animals. So the two floors of animal quarters. I had I didn't have the floor to myself, a whole floor to myself before I went off to war in 1943. It was only when I got back and I needed to really expand my activities, I had a floor to myself with laboratories with all the things that I needed. And I had two floors of animal quarters because those were the days when a virologist had to use animals, and you had to have room, space, for thousands and thousands of mice, and ultimately for hundreds of monkeys at anyone time because I used thousands and thousands of monkeys, and room for chimpanzees and for all that. Now, the only thing that I got from the Research Foundation was my own salary, and perhaps a couple of thousand dollars of fluid funds to be able to do what I liked that I couldn't do with funds let us say from a grant support. But, I was completely autonomous. This, I think, is important. I still stress that as being important. In what I did, because I went--I got my own money ['rCDmdifferent sources after World War II, you know we didn't have the National Institutes of Health and federal support programs at the time. Before World War II, when I came from the Rockefeller to Cincinnati the money came from the National, the new National Foundation for Infantile Paralysis. When I returned, the money came from two sources: the Armed Forces Epidemiological Board to support all the work on the arthropod borne viruses and encephalitis, things that were continuing, and the National Foundation for Infantile Paralysis specifically work having to do with poliomyelitis. I had complete autonomy in decision on how to use the money, what to do, whom to hire and how many to hire and I had the money and I managed it. I had a very excellent relationship with first the original l1\~ director, Dr. G~ Mitchell, who died within two years after I came and then after the interim when Dr. W68ch came to be the Head of the Department of Pediatrics and Director of the Research Foundation, there really grew up an affectionate relationship of mutual respect and admiration which lasts until

this day. Dr. Wecch--

Q You just get along well with pediatricians. A A few months ago, he celebrated his 80th birthd?y. He is continuing still as a post-retirement professor at the University of Florida at Gainesville and it is a really warm, affectionate relationship. At one point there was a question of the extent to which I would need new space to develop a growing program, and there was disagreement that actually I had forgotten until I saw a letter--I don't know how it turned out that the first big application for five years that I made to the National Foundation for Infantile Paralysis--it was a question of putting up another floor, and the money that it would cost, and a judgment was made against the Foundation's using ihs own money. It would come to almost a quarter of a million dollars which was a lot of money in those days. But I must say that I enjoyed the complete autonomy that I had. I participated in conferences and other things, but I must say not as much. When I first came to the research foundation, I was studying directly clinical--certain clinical manifestations like rheumatoid arthritis and the very young who had rheumatic fever and I had special beds, or the various encephalotosphies. I had very close contact with the cl~nic. Later on, it came to be something else. I was studying for example, infections, febrile illnesses of unknown origin. I was studying polio. I was studying the diarrheas, that were prevelant during the summer. So I always had a close contact but very specific. I didn't take time out to make general rounds. I didn't take time out to attend conferences in which I was not directly involved. I am afraid I was--

Q You didn't teach.

A concentrate. I would give lectures occasional_lectures more inspiration lectures, but not as any set thing. I had no set responsibilities.

Q In other words, did you have to give annual reports as to what you were doing?

A Yes, annual reports because we had a very excellent scientific advisory board in the research foundation. It was the top people in the country this was an old tradition. But they were basically the same kind of reports that I would give to the sources of my grant--didn't develop anything special.

Q Let"s turn to the grant sources because in essence they are interesting. Certainly, one of the important grant sources was the fiational ~oundation. Now, did you meet with O'Connor, or were there special people in the foundation to whom you wrote.

A You see, I had an old relationship with the foundation because while I was still at the Rockefeller Institute, and Dr. Rivers, who became one of the important advisors of the national foundation along with Paul De Kr~~ before he was "assassinated" ..•a.s.s.a•ssinated in quotation marks by Basil O'Connor. I was picked out as a promising young man, but the Rational ~undation which just started--it was 1938-- he should be helped to develop a great career in virology and thereby ultimately help the overall problem of polio. So that I was taken to meet Basil O'Connor in 1938 and I had an intimate relationship. Their plan was to send me off to Sweden for three years to work with biophysicists, the great biophysics groups in Upsala. Actually this was to follow an example which was done with Horsfa.~, Frank Horsfa.~ was sent there for years. I was to go there for three years--I would teach them virology. They would teach me biophysics and so on, and I would come back a real hot shot high berth to make important advances. That was of course, it came to a head in 1939. Early in 1939 war clouds were brewing, and I had to make a decision between staying at the Rockefeller Institute and coming to Cincinnati, going to Sweden. I selected to come to Cincinnati--I won't--I think we covered that once before.

Q No, we covered that.

A So that my association, long before I needed money from them, I already knew Basil O'connor. I knew Tom Rivers. I knew Paul De Kr~•uf, and only later did they get people like Harry Weaver and so that I was in with the group. And basically, I was in with the group that was set up to decide the grand policies, the overall policies of the foundation, so it was more of a personal relationship in working things out, t~ ~~ ~arker, the overall program the foundation was supporting. Those were the years before Basil O'Connor had developed a special affinities and I would say that the relations were very very good.

[...]

Interview with Dr. Albert Sabin

May 22, 1976

A Supplement to our discussion of May 14, May 15 in which the work covered by the semi annual reports of January to December of 1953 had been covered. The important observation mentioned there was that the MEF(1) mouse adapted virus from Dr. Olitsky's laboratory had been found by me to be non-scitopathic for monkey kidney cells in tissue culture. But, that without destroying the cells, without being scitopathic, it nevertheless imparted a resistance to super infection. I recalled at that time my publication in 'Science' of work that I did very shortly after the publication of the discovery of Enders, Weller, Robbins of the capacity of polio virus to multiply in tissue culture in non-nervous tissue. And I wanted to know why did my own studies in 1936 not pick up this question. This phenomenon. So this is the publication, less than a page in 'Science' of August 27, 1954 under the title "Non-scitopatho-genic variants of poliomyelitis viruses and resistance to superinfection in tissue culture." Now I am going to -- just a moment stop.

I am reading here from the publication in 'Science' of August 27,1954 on non-scitopathic variants of poliomyelitis viruses and resistance to superinfection in tissue culture.

Ever since unequivocal multiplication in non-nervous tissue was demonstrated by Enders, Weller and Robbins thirteen years after my own experiment in 1936 failed to show any multiplication in non-nervous tissues, it had been an intriguing question why those 1936 experiments with non-nervous tissue -- that is, human non-nervous tissue -- had failed. My own recent experiments had demonstrated--incidentally, as an aside here I am modifying a little bit the reading to bring it more --

Q Sure.

A My own recent experiments have demonstrated that intracerebral passage in monkeys favors the segregation of variants that are devoid of scitopathogenic activity for fibroblasts growing out of monkey testicles in tissue culture but possess full scitopathogenic activity for epithelial cells derived from monkey kidney.

So that was a little difficult to understand. It still did it in monkey kidney although it didn't do it for fibroblasts and testicles.

Now more recently I have found that from the nervous system of infected animals it is possible to segregate variants that have no scitopathogenic effect on epithelial cells derived from monkey kidneys.

This again is an aside, pointing once again to the multiplicity of potentials in individual virus particles in a population of polio virus In a culture. Then I continue.

Since the MV strain of virus that was used in 1936 -- in the 1936 cultivation experiment, that had a large number of intracerebral passages. I have just noticed a mistake in the reprint. That should have read intracerebral, and it says intercerebral. In monkeys it appeared possible that it might be a variant. "It" means the mixed virus, the MV strain of Flexner's might be a variant that lacked the property of multiplication in non-nervous tissues. This also is important because of the decades of work with this strain as the prototype of poliomyelitis virus in man. Of course this was the thing that I have been struggling with and at the end of my stay at the Rockefeller Institute. A specimen of this mixed virus that had been frozen for many years was found to have had no scitopathogenic effect on epithelial cells derived from monkey kidney in any dilution tested -- the reason for that is to look for a zone phenomenon in the case of the mixed population that you, of virus particles that you had picked up.

Although intracerebral inoculation of this stored specimen that had been frozen, produced typical paralytic poliomyelitis in the monkey. Now the freshly passaged virus obtained from this monkey also produced no scitopathogenic effect on monkey kidney epithelial cells and four blind passages failed.

passaged virus obtained from this monkey also produced no scitopathogenic effect on monkey kidney epithelial cells and four blind passages failed.

Blind passages, that is in epithelial cell monkey kidney epithelial cell cultures -- failed to yield a scitopathogenic agent. Although in the third and fourth passages a few epithelial cells degenerated and fell off the glass within four days after inoculation. Whereas the bulk of the growth remained unaffected for ten to twelve days. It should be noted for your, Saul Benison's benefit that the significance of that is that you get a scitopathic effect with a high concentration of virus within 24 hours and it if the concentration is low, you didn't get it. In four days and certainly minute amounts will appear at 70. But this is ten to twelve days, and nothing happened. Then I say here last year, I observed, that would be 1953, that a strain of MEF(1) suckling mouse adapted poliomyelitis virus and this was the strain that was adapted in Dr. Olitsky's laboratory

by Slesinger --

Q And Kosalls

A And Kosalls. Derived this strain, was derived from the viral progeny in a single suckling mouse -- this is, I selected this myself in terminal dilution at the end point of an intracerebral titration in suckling mice, exerted little or no scitopathogenic effect on monkey kidney cells. Notice the point of little or no. It doesn't say no. But after an incubation period of seven to twelve days, the majority of the epithelial cells that had been exposed to the virus even in dilutions as high as one to ten million to one to a hundred million of the suckling mouse strain had become resistant to the rapid -- not the word rapid -- scitopathogenic effect of the parent MEF(1) strain that means the monkey, the original monkey brain pass~ge virus before it had been submitted to adaptation to suckling mice. Now similar tests then performed after I had noticed that. It was then that I went back to the mixed virus. Similar tests performed with the MV virus revealed that after an incubation period of ten to twelve days in roller tubes the epithelial cells derived from monkey kidney had acquired a limited resistance to the scitopathogenic effect of one hundred TCD(50) of the homotypic type 2 YSK strain.

And here is what one saw. At two days after challenge the epithelial cells in the control tube at two days as well as in the tubes that receive very high dilutions of the MV virus. This is from monkey spinal cord. Were completely destroyed. So the ordinary process, two days, everything was gone. The epithelial cells in the tubes inoculated with the lower dilutions of MV virus. That is lower dilutions of spinal cord of the monkey. Showed little or no change in two days. But at four days almost all the cells were similarly destroyed. Now this is a little different from what I observed and previously described with the MEF(1) strain. You see, there are again differences here. Between the MV, which was monkey brain adapted and the MEF(1) which was suckling mouse brain adapted. The epithelial cells in the tubes inoculated then with -- but at four days you see there is then a prongation, a temporary inhibition. This limited resistance characterized by the period of delay was not observed when a mixture of the MV, that is non-scitopathogenic and YSK viruses was added to normal epithelial cells. That is at the same time. Nor was this observed when the YSK virus which is scitopathogenic was added one hour or six days after the addition of MV virus. Now the importance of this is as follows.

The fact that this was not observed when the scitopathic virus was added one hour later meant that some molecular, biological event had to take place as a result of the reaction between the MV virus or the MEF(1) virus with the cell that took more than hour. Because if you added the scitopathic virus one hour later it didn't happen, you see. So obviously this shows that some event that interfered with the normal proliferation of virus had occurred and required more than an hour. The fact that it did not occur six days when the scitopathic virus was added six days after the MV virus means that that transitory change, biological change that in the first that it was transitory, that it was not a complete resistance that was imparted onto that cell. So these are important observations by themselves indicating somewhat the nature of the interference that the strict neuratropic virus exerts on the cells and a nonnervous cell growing in tissue culture. Of course I am not reading all of this from the --

Q No, you interjected.

A I am interpreting in the light of more recent understanding. My final paragraph says, it should be noted here that strict neuratropic variants that have recently been segregated in this laboratory--this was during the course of my many experiments from type 1 and type 3 viruses--have conferred no such resistance on epithelial cells derived from monkey kidney. But it is possible that the challenge viruses may not have been added at the right time. This again shows the very involved biological events that take place in a cell after infection with polio virus. And it also suggests that the strict neuratropes probably go into the cell, that they do not merely occupy a receptors that some step is interfered with. And it may be that not all strict neuratropes have that capacity. Not all strict neuratropes have the biological characteristics that are similar. They are only similar in that they will not produce a scitopathic effect in non-nervous tissue. I go on to say from these observations that further work on the mechanism of resistance produced by non-scitopathogenic variants of poliomyelitis virus would be of the greatest interest particularly with respect to the possible operation of a phenomenon comparable to that of licogenic pharge (?).

I personally did not pursue that any further. I have finished reading this now. Again, because this is an example of somebody having to make a choice. Make a choice whether I wanted to pursue, go in the direction that I have already set out, the main line of my work or to go off on a tangent and find out what is it that happens in a cell infected by strict neuratrope, stokey variance (?) of poliomyelitis virus. To the best of my knowledge this observation had never been picked up by the molecular biologists who studied in very great detail. Of course the work of Baltimore on the minutest detail of the biology of replication of polio virus in cells which added very much to our knowledge not so much about polio virus for the control of polio virus as a disease, as a cause of the raising of disease but for basic understanding biologic phenomenau He .punsued that very extensively. This was part of his Nobel oration, the description of that work. And yet just what different mutants of variance of polio virus do particularly those who do not multiply to the best of my knowledge, and I have now checked the literature, has never been followed up. And I am sure that it would throw considerable interesting general biological light on the interaction between viruses and cells at different phases of replication. So much for this. If you need this --

Q Dr. Sabin, before you leave that, let me ask a question that almost seems -- you have never had any formal training in genetics before undertaking this, this kind of work.

A Let me answer this as follows. I never had any formal training in genetics except laboratory. You see in Medical School nor was that the period in which the tools for studying the molecular biology of viral replication were available. Nor may I say that I trained myself in fundamental genetics but fundamental--this is Mendellian genetics until years not years later but actually it happened before I must backtrack a little bit because I am not sure. I think we covered it in a previous chapter when by accident during my work at the Rockefeller Institute at Princeton during World War II, I discovered the complete resistance genetic resistance of mice bred out, white mice bred out at the Rockefeller Institute at Princeton to yellow fever virus and then other viruses by comparison to the same original stock of Swiss mice that were bred out at the Rockefeller Institute in New York. And then when after the war was over I went back to study the genetics of this resistance it was then that I trained myself so it isn't correct to say that in 1953, 54 I had no training in genetics because I trained myself. Because my publications with beautiful genetic laws operating in resistance to infection with yellow fever virus and with dingue virus and certain other viruses in the same group forced me to train myself in genetics so that I had that training by the time that this work was done. It was enough to make me think genetically in terms of the multiplicity of potentials of individual virus particles but this was not a situation that was comparable to here is a, one

kind of a pea and here is another kind of a pea and I cross the two and what do I get. What do I get. This I was able to do. I crossed white mice with a 100% resistance to, resistant to yellow fever virus with mice that are 100% susceptible. I study the Fl generation. I study the back crosses. I study the F2 generations. I study the mechanism involved. That was a genetic study. But here, this was a different kind. This had nothing to do really with genetics as such in the classical style as you say. It had more to do with the biology, molecular biology and the chemistry of the phenomenon that go into operation when a virus particle hooks up by proper receptors to a,~susceptible cell and then a whole chain of events can either happen or not happen or be interfered with, depending on the nature of the virus particle. So this is quite another aspect of genetics. It hasnothing to do with inheritance and certain characters when virus particles are crossed. Or, as in the case of influenza when two virus particles with different genetic material infect the same cell. It is quite a different story. A pursuit of the observations that I just described further to analyze the mechanism at what stage, what happened, could have yielded an understanding of the steps involved in replication of polio viruses in cells just what it is that some strict neuratropes lack that prevents them from multiplying in a non-nervous cells and what it is that they nevertheless do in that cell that interferes with the multiplication of those that can multiply in that cell. Well, so much for general biology which I did not pursue in this particular instance because of the over riding priority in my own judgment of the other things that I had decided to pursue. Now there is--it is an important principle if I may bring this out --

Q Oh, please.

A In the life of a scientist. Because subsequently as a so-called administrator especially, I ran into this the wife's

penance to his science [???] and I had to think about this problem. And even now because in a scientist's life there are many occasions when you can ask more questions than you can handle. And there are many scientists who simultaneously try to work on ten, twenty differoent things at the same time. The same ones. Alright they may have a lot of hands doing many other things. And this by and large is not productive. When I analyze the work of people who tried to spread themselves allover the place they accumulate a lot of pebbles but as a rule--not always--I am saying as a rule they do not end up with any meaningful structure, with any meaningful, larger contribution. And the reason for that is that they had not made up their mind out of the ten or twenty burning desires that they have, which one they should concentrate on. And this is a good example of in my own case, I am also guilty of having tried my hand at many things at the same time. I am not trying to throw stones at others. But this is a constant problem with me, and in this case I made a decision that, not to divert myself more than is absolutely necessary to get to the answer of the problem that I originally defined.

Q You see me turning pages and what I was turning for was to find something I had marked down and it bears on what you have just said. You found a variant that had an uncogenic effect on helocells and I wondered why you didn't pursue that. It looked like an interesting--

A Saul--there is something wrong in this statement a priori. I did not find a variant that was uncogenic for helocells because helocells are malignant cells.

Q Yes.

A So it couldn't be a variant. I don't know what you have in mind.

Q Let me shut this a minute. [...] Dr. Sabin, in your semi annual report to the National Foundation for the period of January 1, 1955 to June 30, 1955 on page 4 at the bottom of the page under item number 5 you have said the following. Many unclassified viruses have been recovered from the stools of chimpanzees during the course of our poliomyelitis studies. One of these strains was sent to Dr. Huthner (Huebner) who was looking for non-human viruses to use for experimental therapy of human carcinoma of the uterus. This chimpanzee virus whilescitopatogenic for helocells and human sera contained no antibodies for it. In preliminary tests it produced extensive destruction in uterine cancers. The point of this observation is that a battery of antigenically distinct chimpanzee enteric viruses for which human beings would have no antibody might lend themselves to consecutive administration in tests for their destructive capacity in certain human cancers. And I wonder if you would comment on it because I think it bears on what we have been talking about.

A I would like to comment on this because it represented a very important effort during that period in which an attempt was made to use viruses to destroy human cancers. Should I continue on this--

Q Please, please. We have plenty of tape.

A Alright. Now here is the background of this. When tissue cultures came into use for the isolation of viruses and it opened up Pandora's box progress, one of the cell lines that was used very commonly because it was easy was used for polio as well as other viruses was the helocell. The helocell was regarded at that time as having been derived from a carcinoma of the cervix of the uterus. Cervix of the uterus and perpetuated. Now, in the study that subsequently followed in various laboratories and particularly Dr. Huebner and the National Institutes of Health pursued this. It was found that many of the ~o-called echo and coccaski viruses that were being isolated from human stools had an effect not only on helocells but on other cell lines derived from human cancers. There are not many. But, so the question naturally arose, would it be possible to use such viruses in human beings-- viruses that would be, not be harmful to the human being to destroy a cancer in the living animal. If these relatively inocuous orphan viruses as they were called at the time, could destroy cancer cells in vitro much better than any drug that you could find, why not use them in the human body to destroy cancers. Some experiments had been done in model systems in which it was indeed found that this could be done. I myself carried out an experiment which was reported in the literature. I don't know whether we discussed it earlier with Alice Moore.

Q Hold it. Hold it. Go ahead.

A Of the Sloan Kettering Institute. It had been found that a transplantable sarcoma of mice--the sarcoma 180 was very readily destroyed by Russian spring summer encephalitis virus. So that if you had a mouse that carried this tumor and you inoculated it with Russian spring summer encephalitis virus that localized in the tumor, it destroyed the tumor but it also killed the mouse. So you didn't know what was going to happen. But then I found, and this relates to our previous discussion, that when we used the Princeton Institute mice, that were genetically resistant to yellow fever virus and to certain other viruses which included Russian spring summer encephalitis group, it was possible to inoculate the virus and the mice would not die. So the question arose, what would happen in a mouse, a Princeton Rockefeller Institute mouse, a resistant mouse that would not die of Russian spring summer encephalitis but which was carrying a big tumor of sarcoma, a transplantable tumor sarcoma 180. Dr. Alice Moore at the Sloan Kettering Institute was working with this. So we transp~ anted some sarcoma 180 into Princeton Institute white mice; they developed big tumors. And they were inoculated with large doses from varying doses of Russian spring summer encephalitis. Well, to make a long story short, the virus dissolved the tumor. It did. Because the tumor was genetically different from the mouse, even though it grew In it. It was well adapted to growth. And the virus multiplied to a very high level in that tumor and destroyed most of it. The mouse survived. So that was in an era, you see, where this was under considerable discussion and there were some seminars devoted to it. One of the problems was that if you used viruses that were commonly disseminated among human beings that you would not be able to find human--that the vast majority of human beings had immunity to them, and that it wouldn't multiply in them. Now you can't use a virus like Russian spring summer, it would kill them, you see. There were some other experiments tried with Wes Nile for example, so when I run across in the stools of chimpanzees a virus that kills

HeLocells in tissue culture and for which as I said, human beings have no antibodies, I say why isn't this a wonderful opportunity. Here we have a virus that will destroy these cells and we have no problem of immunity in human beings. And that is why I turned it over to Huebner who by that time after many studies in model systems in mice had already begun to collaborate with surgeons who did a very wonderful thing. In order to prevent too much of the virus being distributed throughout the body before it got to the tumor itself, they would isolate the arterial supply to the tumor and actually inject the virus into the artery supplying the tumor and they had found already with some other viruses in patients who had no immunity that this would indeed punch a hole in the tumor. It would eat away much of the tumor. Pretty much the way certain chemotherapy would do. But the problem was, that no sooner than that hole was punched, and as the individual developed immunity to that virus, the tumor cells began to grow again, and after a couple of months you were no further ahead. A situation not unlike that with chemotherapy. So, during a symposium that was held during that period at the M. D. Anderson I proposed the following strategy. I always was influenced. This is an aside. By my training at Carlisle Barracks as a medical officer. I didn't get much basic military strategy but it had an impact on me because there was very much in that strategy that has to do with an attack on human disease. So I thought that the following strategy may be worthwhile. That if one virus will destroy a large number of tumor cells in an existing tumor and then it stops why not come in with a second blow. In other words, you have the first group of troops advancing, just opening up a hole and then before that hole can be filled in by the enemy, come in with another one and destroy the others. And with a third one and with a fourth one. So the suggestion that I made was that one should not give up this work simply because the body becomes immune and you cannot destroy the tumor completely. The strategy that I proposed is that we should develop a battery of viruses. Viruses that would be non pathogenic for man, and when you are dealing with patients who are going to die of cancer anyway, the problem is not so great. And just give them one after another. After one knocked out a part of a tumor, individual is immune. Give them a second one. Knock out some more. Give him a third one. Knock out some more. Actually years later, this became the approach of chemotherapy, you see. But, this~was not pursued. So when I say in this report that Dr. Huebner reported to me that this virus that I casually picked up, or accidentally picked up from the stools of chimpanzees did produce an effect in destroying uterine carcinoma. Actually it is cervical carcinoma, I felt that it was not pursued far enough by the virologists who took this approach. They left the field to chemotherapy. And I am not at all sure now more than twenty years later that that approach isn't at least as good as the approach that is being made by chemotheraphists against cancer. And may indeed provide additional weapons but it does require the development of a battery of viruses which can be given one after another with a destructive effect on a particular tumor cell. Period.

Q Not period. I have--

A I want to say here--

Q Okay. Well I find interesting the problem is interesting. You are not seduced by it.

A Well I am not seduced by it because we are back to where I started. The decision whether an individual scientist has to make who is interested in carrying his work to the meaningful end point, to an end point of decision that if I would suddenly drop everything else and go off and pursue this particular thing which at that t~me was already being done by Huebner and others, that I probably would lose the imput that I had already made on a~major objective. The point was that if a scientist works all sorts of interesting observations arise on the side. Sometimes they are more important than the original objective. My judgment was that my original objective was more important than this. And that I had to concentrate the efforts on the original objective until a yes or a no answer would be available. Mind you this is 19--the work was done in 1954. I was still a long way from knowing which way it would go. But I am very glad I made the decision. Although, I just finished saying that I think that that work was left prematurely, that it was still desirable because of our lack of knowledge of how to prevent cancer to use in addition to chemotherapy to use what I would call viral therapy of cancers, viral therapy of cancers and selecting viruses paricularly the many orphan viruses from closely related primates that would have a destructive effect on cancer cells in vitro--using them one after another. This is a variation of the strategy. Now this is not without difficulties because unless you carried out very careful studies beforehand you might run into a virus that might be very pathogenic for man. And this is one of the reasons that the work really again was left. Of course some of the chemotherapeutic agents they are using now are pretty damned awful. I doubt whether there are many virus diseases that can produce the serious side effects as the chemical agents.

Q Now period. Dr. Sabin at this point I would like for you to read into the record a letter of October 3, 1955 which is a summary letter. And I think an important letter.

A Actually it is a supplementary letter. I is addressed Dr. Koom of the NFIP in which I s~y that in adcord with your request I am sending you herewith a brief progress report to supplement the semi annual progress report and the information contained in my letter of September 10 all this for presentation to the committee on virus research and epidemiology. The first topic is the search for strains possessing minimal pathogeniticity for monkeys by the spinal route. Since the semi annual report was written three such strains turned up during our screening of poliomyelitis viruses reoovered from the stools of healthy children. I should add which we ourselves recovered from the stools of healthy children. The stools having been obtained from Drs. Fox and Gelfain in the New Orleans region. This included two type 1 strains, one designated P-2149 and the other P-2226 and one type 2 strain designated P-712, Seven, twelve. That is seven twelve. It 1S just one. Now the search for variants capable of producing the scitopathogenic effect in capuchin or capuchin monkey kidney cells revealed that some, but not all type 1 strains may possess a few particles out of a very large population which can produce

a scit9pathogenic effect in capuchin monkey kidney cells. These particles have been segregated from the others and passaged in a series, in series in capuchin monkey kidney sufficiently to get away from the original population of virus particles derived from cynamologous monkey kidney cultures. Although tests on several strains are still in progress those that were completed on one type 1 strain indicated that the particles which have the special capacity for producing the scitopathic effect in capuchin cells are as pathogenic for monkeys by the spinal route as was the parent virus. Let me digress here. This is an example of the attempt to pursue every possible selected medium that might provide polio virus particles with different properties. The ideal properties we were seeking. And this is the main reason for having pursued this. And this is an example of population genetics of virus particles, polio 'virus particles population genetics is quite different from the genetics of individuals. Alright. I go on and say although tests on two other strains are scheduled for the near future it would now appear that this approach is not promising and will therefore not be pursued further in 1956. It had to be done. It was done, and out. Further work in progress on attempts to find variants which will propagate in chick embryo indicates that this is not a promising line of work and will not be pursued in 1956. Additional observations on human volunteers. Most of the men who were fed the experimentally segregated attenuated poliomyelitis viruses in January 1955 were available for a check on the level of their antibody six months after ingestion of the virus. As an aside I want to say here that this was refers to work we have not yet discussed in detail. This refers to the work on human volunteers in the Chillicothe Federal Prison. Now I continue from the letter. In all instances the titers were either the same. That is the titers of antibody, six months after ingestion of the virus were either the same or higher at six months than at three months. In a number of instances the higher titers eccurred in those volunteers who were fed a second type of virus three months after the initial ingestion of another titer. As an aside I would like to say here this is an important observation that was followed up later which indicated that you can get a booster virus against--not a booster virus--a boost of antibody titer when you are infected not by the same type but by another type. In other words that the cross relationship between the three distinct types of polio virus is such that you may get a temporary boost let us say in type 1 antibody even though the infection was with type 2. And this is still until this day not understood because the assumption is that In an unknown patient if

he has had a--he shows a boost, a rise in antibody for type 1 he had an infection of type 1. It is terribly important and it became important subsequently during the mass trials when one tried to determine the nature of intercurrent paralytic disease to decide what a rise in antibody meant. Did it mean that that person was infected in nature with that particular type. It doesn't. That is what this work showed, you see. I am going back to this.

Q Go ahead.

A In my letter of September la, I wrote you of a new series--excuse me again for stopping here. I keep speaking of my letter of September la, and yet I don't have a letter of September 10. I read into the record a letter of June 25, 1955

but nothing. I have no copy of a letter of September 10, and I don't know what I said in my letter of September 10.

Q Alright.

A Would you stop this a moment?

Q Yes, yes.

A We have been unable to locate the letter of September 10 so I will just continue reading from the letter of October 3. And this paragraph, this paragraph begins In my letter of September 10, I wrote you of a new series of tests which were to begin at Chillicothe on September 13. A total of 27 men were used. Six men were used for each of the three type 1 strains that were tested. That is LSC P-2149, and P-2226. Six men for the type 3Glen strain. Parenthetically this is a strain isolated from a healthy child in Cincinnati that was relatively avirulent to begin with. And three men who lacked both type 1 and 3 antibody received a mixture of equal amounts of type 1, P-2149 and type 3 Glen viruses. Each strain was tested in a dose of 0.1 ml and O. and one thousandth of an ml. The viruses this time were fed in a cherry syrup rather than in milk in the hopes that this might lead to a larger number of virus particles being trapped on the throat. It is interesting. From the results that have been obtained, it would appear that this was achieved although one cannot be certain to what extent the strain of virus might have played a part. At any rate while none of the volunteers who received virus in milk in January from a dose of 1 thousandth ml had virus multiplication in their throat. Six out of eleven of the present group presented evidence of viral multiplication in the throat after ingestion of one thousandth ml. Alimentary infection was established in all volunteers ~n:the test performed on serial bleedings up to two weeks after ingestion of the virus indicated that all but one developed antibody. Many of them within one week after ingestion of the virus. The one who thus far has not developed antibodies received one tenth ml of the LSC virus and has exhibited very active viral multiplication in his throat and lower alimentary tract. Let me digress here. This is one of those many observations that I encountered in several hundred volunteers I studied who didn't follow the classical concept. The classical concept is that polio virus multiplies; antibody appears within about a week, etc., etc. That is classical alright because that is the way it usually happens but there are these exceptions that we must remember. And here is a beautiful one which we encountered again later of where the dose of virus that is fed is big, active viral multiplication goes on in the throat and lower alimentary tract, but he had not developed antibodies. So the mere absence of antibody is by itself no proof in anyone person statistically it may be significant. But in anyone person it doesn't mean that he didn't have a previous infection with the virus. That is determined only by his response to subsequent infection. Now I continue reading from the letter now. Many of the volunteers, particularly in the group who received I say here who received P-2149 virus developed an antibody within one week after ingestion of the virus. Of special interest is the fact that all three volunteers who were fed a mixture of about one millionth TCD50 of the type 1 P-2149 strain and the type 3 Glen strain developed antibodies for both type 1 and type 3 strains. This lack of interference in the case of these two strains in human volunteers is to be contrasted with the complete suppression of the multiplication and antibody response to the type 3 Leon virus when ir.was fed to chimpanzees with a mixture of our Mahoney and YSK attenuated viruses. That is with type 1 and type 2. Preliminary tests on the current human volunteers already indicate that apparently both type 1 and type 3 viruses multiply simultaneously in the pharyngeal wall. However, many additional tests still remain to be done before a complete picture will be available. I want to digress here a moment, because these statements in this letter here are a reflection of the numerable facets that had to be elucidated. The numerable questions which are just as basic as any other questions would have to be asked as to what would happen if you would feed these strains separately, if you feed two together, if you feed the three types together. Are there strains which may interfere less with one another--all of that work had to be done in advance of any decision of rushing out and administering the first strain of virus that you had that looked like a plausible candidate. When I read back on this now I am amazed at the tremendous amount of preliminary infrastructure studies that I believed were necessary that we carried out and that provided us ultimately with a spectrum of knowledge about the behavior of polio virus strains in the human alimentary tract that is still up to the present time not properly perceived by my colleagues who have not done all of this work because I have never written a monograph in which I documented everyone of the experiences that have left such a deep impression on my own thinking.

Q Now since you have raised this question of infrastructure of research--

A Of knowledge.

Q Knowledge. For example, by the end of 1953, beginning of 1954 you have several strains which are avirulent on spinal inoculation in chimpanzees. Why do you continue research for a variant that is also avirulent for monkeys?

A I think this question was touched upon before and the answer is simple. The striving was to determine whether any strain we possessed or anybody else possessed could be as nonneurotropic for the most highly sensitive primate and still multiply in the intestinal tract enough to produce (a) the systemic immunity that we were measuring and looking for as well as the resistance to reinfection that is an essential component of the whole challenge of breaking the chain of tansmittance. We did not want to give up. It would be very easy to say alright, this is good enough. But it was necessary to continue. You have to have here a judgment how long do you continue, and when do you stop. And I would say the judgment depends on the results that you gain from ace~bain effort. If yow. continue too long and you don't do anything. That's not very wise because you may never get it. You might get it. As a matter of fact, I continued. I did continue as I think I remarked before after the worldwide tests on increasingly larger numbers of human beings were already in progress. I did continue after the vaccine had already been administered to over 100 million people in the world. I did continue with the search by cold adaptation, by getting viruses that wou~d multiply at 25° which they ordinarily don~t. And did succeed in obtaining mutants that even on spinal inoculation in monkeys were not active, that produced practically--were not paralytogenic. In other words, I achieved that. And then I continued with the experiments in chimpanzees and finally feeding to children and they turned out to be much worse from the point of view of quick reversion to larger numbers with increased virulence in the human intestinal tract that we had selected. So, we did achieve finally strains that were inactive on intraspinal inoculation in the monkey but they were no good. For other reasons. Okay.

Q Go ahead.

A Now, we go back to the letter of October 3, 1955. And the next,the final, the beginning of the last paragraph on page 2. I say tomorrow on October 4, a new series of tests are scheduled to begin on another group of 20 volunteers at Chillicothe. Let me digress here. The numbers of volunteers that could be used at

anyone time in Chillicothe were influenced by several factors. We were dealing there with young adults. Some of them had immunity already naturally acquired immunity to all three types of polio. Some lacked immunity for one or at least antibody for one or another type. So we had to constantly screen new numbers because there were, I forget, a couple of thousand young prisoners in this federal prison. We had to screen them, bleed them ahead of time, find out those that were without antibody for the type or types that we were going to test. And then there was another constraint. The warden of the prison said all of these prisoners are working and you cannot disrupt my various activities in the prison by taking out too many people. You can have so many at a time. Alright. So that is the reason for some of the numbers that we used. So another test was to begin on another group of 20 volunteers at Chillicoth. Twelve men will be used for the type 2 strain, P-712 in doses ranging from one tenth to one thousandth of an mI. This is the standard, preliminary. One man who is without antibody for all three types of polio-- they were rare as hen's teeth in that age group and in that social group--will receive a mixture of all three types. Four men who are without antibody for type 1 and type 2 are receiving a mixture of 1 and 2. And three men without antibody for types 2 and 3 will receive a mixture of types 2 and 3 virus. The studies on both groups of these volunteers should be completed by the end of this year, and at the end of that time we may be in a position to decide ~hich of the strains are most suitable for further progressive studies in human beings. An emphasis on the step by step approach. I continue from the letter. At this time we are testing in monkeys. Always the first step, monkeys, chimpanzees, humans. At this time we are testing in monkeys two additional type~:3 strains which were recovered from healthy children in the New Orleans area.

Q This was Fox and Gelfain.

A Yes. Only if they should exhibit a markedly lower pathogenicity for monkeys by the spinal route than the Glen strain. That is the Cincinnati strain from--that's the strain from Cincinnati children. Now under investigation would tests Ilinhuman beings be carried out. I will digress again. This is an illustration of the indicators for decision. At this stage if it was not better intraspinally than others we had already studied, it stopped at the phase of tests in the monkeys for neuralvirulence. If it had been better we would have gone on tOe the next phase. Now I continue from the letter. As matters stand now, therefore, it would appear that the major effort in 1956. Let me digress again. This shows the constant job of planning ahead and trying to project to a group who has to provide you with the funds and so forth. And it is a necessity. I am not speaking against it--but of being able to project ahead what you are likely to do on the basis of what you know now. What you ultimately do may turn out to b~ altogether different because you don't know what the results will dictate. So that is why I say as matters stand now therefore it would appear that the major effort in 1956 would be concerned with an extension of studies in human beings of the strains that proved to be the optimum ones in the current tests. Thees studies would be essentially the ones that were outlined the memorandum accompanying the 1956 application. It would be my plan to prepare at least ten liters of each of the selected strain, carry out the most extensive safety and control tests on them, and then use aliquots of these basic lots for all the projected studies in human beings. I am digressing here once again, because this has the important principle. It touches on the important principle of starting with a seed lot, a lot big enough so that the variation from lot to lot as it grows will be eliminated; this is an attempt to eliminate as many variables as possible. But you are no~ ready for that sort of thing until you have a potential candidate.

Q Alright. Hold it. We are running to the end of thetape.

END OF TAPE.

Samuel Sachs

Born

July 28, 1851

Maryland, US

Died

March 2, 1935 (aged 83)

New York City, US

Occupation

Investment banker

Known for

Name partner of Goldman Sachs

Spouse(s)

Louisa Goldman (m. 1882)

[1]

Children

Paul J. Sachs (1878–1965)

Arthur Sachs (1880-1975)

Walter E. Sachs (1884–1980)

Ella Sachs (1886-1918)

Parent(s)

Sophie and Joseph Sachs

Family

Julius Sachs (brother)

Bernard Sachs (brother)

Marcus Goldman (father-in-law)

Samuel Sachs (/zɑːks/; July 28, 1851 – March 2, 1935) was an American investment banker.

Early life

Samuel Sachs was born on July 28, 1851 in Maryland, the son of Sophie (née Baer) and Joseph Sachs, both Jewish immigrants from Bavaria, Germany.[2] He has one older sibling, Julius Sachs, and three younger siblings, Emily Sachs, Henry Sachs, and Bernard Sachs.[2]

Career

Sachs, along with his longtime friend Philip Lehman of Lehman Brothers, pioneered the issuing of stock as a way for new companies to raise funds.

Sachs then joined his father-in-law Marcus Goldman's firm which prompted the name change to Goldman Sachs in 1904. Together they underwrote securities offerings for such large firms as Sears, Roebuck and Company. During this time Goldman Sachs also diversified to become involved in other major securities markets, like the over-the-counter, bond, and convertibles markets which are still a big part of the company's revenue today. Sachs retired in 1928.

Philanthropy

Sachs donated US$50,000 (equivalent to $731,000 in 2018) to Harvard University in 1924.[3]

Personal life and death

Sachs married Louisa Goldman, the youngest daughter of Marcus Goldman, also Bavarian Jewish immigrants.[2][4] They resided at The Pierre.[5] They had four children: Paul Joseph Sachs, Arthur Sachs, Walter Edward Sachs, and Ella S. Sachs.[2]

Sachs died on March 2, 1935 in New York City.[5][6]

BANKRUPTCY CASES

A hearing was held before Referee in Bankruptcy Bertolet Thursday morning, in the case of Albert Weber, trading as Weber and Company, on the petition of Ellis Brothers, who have made claim to 100 knitting machines, worth $8,000, which are in Weber's factory. The machines are claimed under a bill of sale with a subsequent lease to Weber. The referee reserved decision.

The sale of the bankrupt's hosiery plant, at Twelfth and Muhlenberg streets, with all of the machinery with the exception of the 100 machines in dispute, was confirmed by the referee. Harry J. Bush was the purchaser, the price being $33,000, less a mortgage of $12,000.

In the case of Charles L. Oaks, the sale of the bankrupt's hosiery plant, 39 Moss street, was confirmed. The mill was sold to Herman Sacks and Harry Steinberg for $11,100.

A hearing was held in the case of C. W. Hershey, trading as the Rotary Manufacturing Co., in which an account has been filed by the trustee. The latter has received upwards of $1,250 from all sources. A first dividend of 25 per cent. was declared, payable July 22.

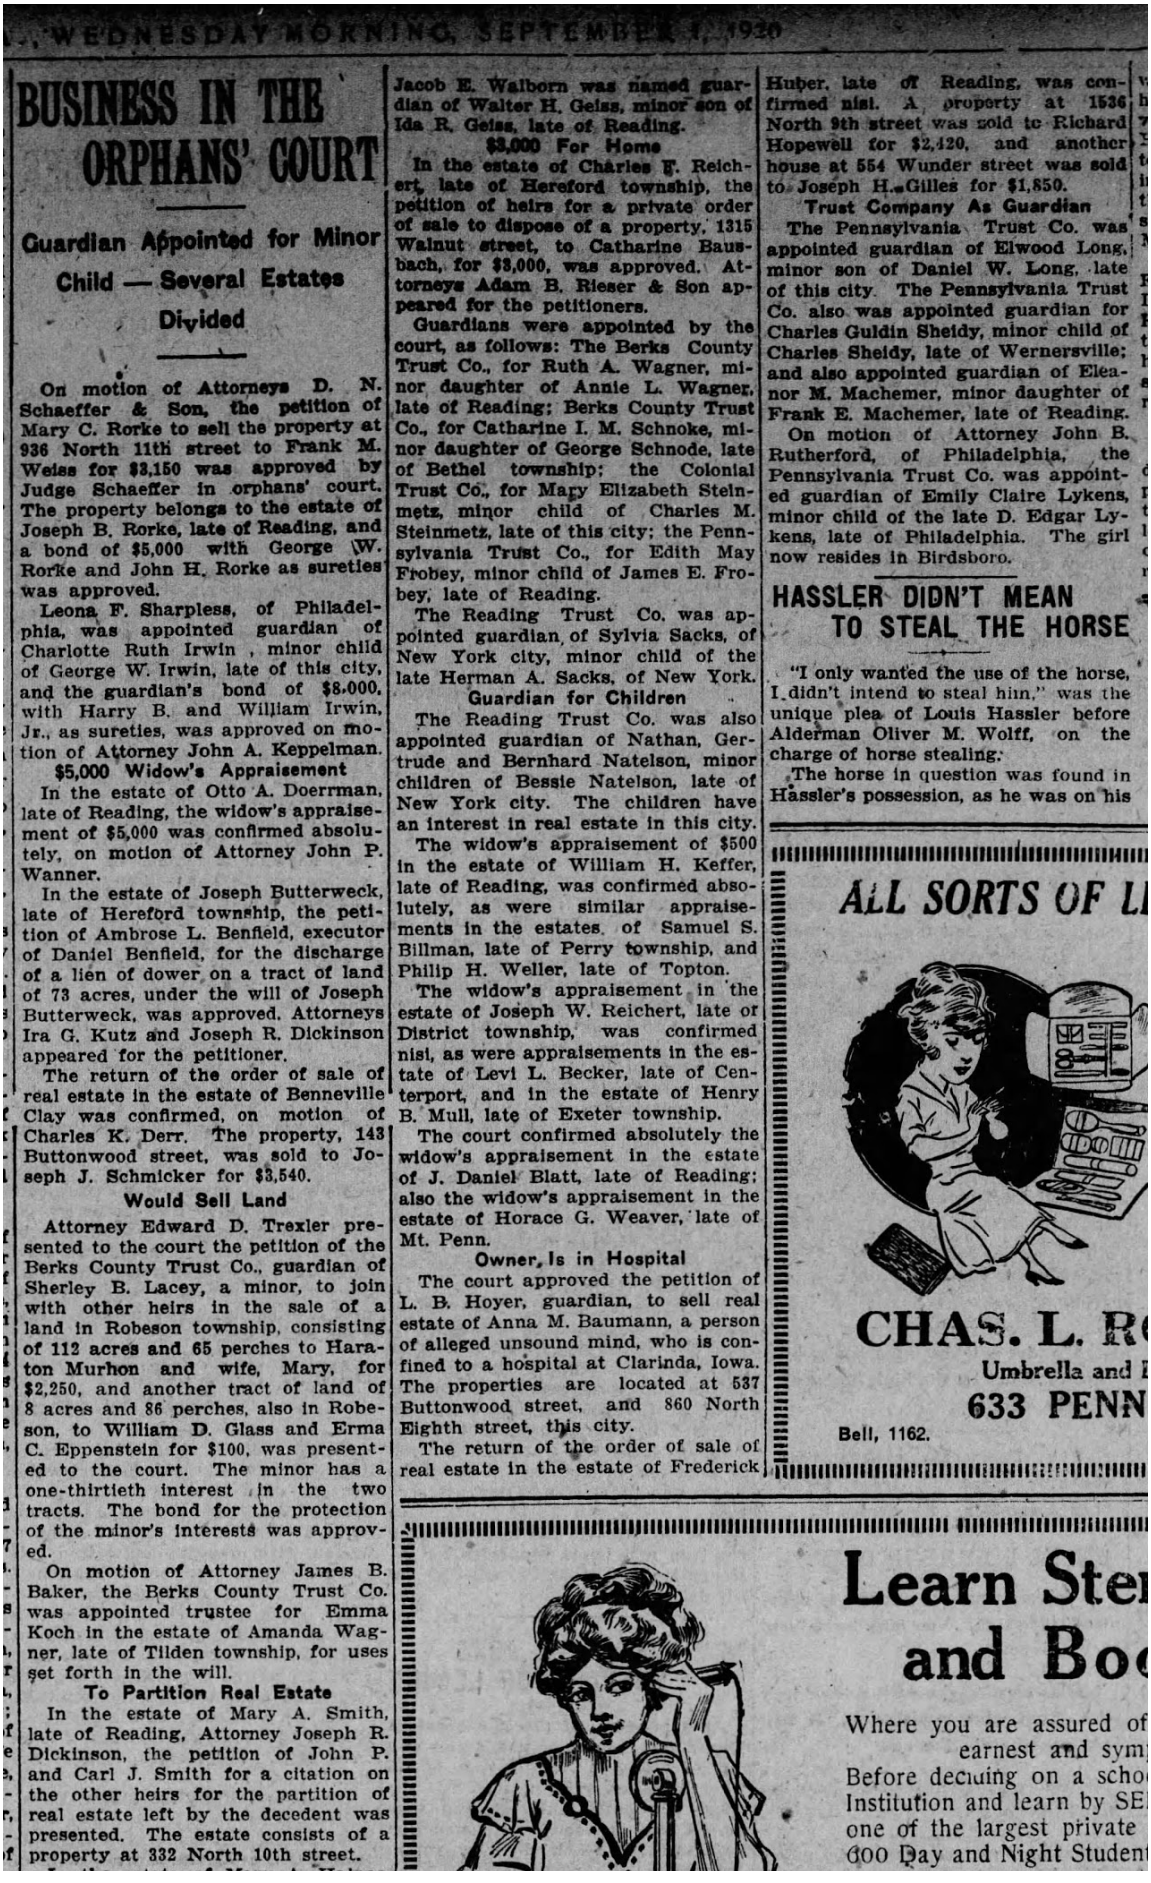
1920 (Sep) - Sylvia Sacks has Reading Trust Co. appointed as guardian

Full page : [HN00HY][GDrive]

Sylvia Sacks was born 1914 (est)

*"The **Reading Trust Co.** was appointed guardian of **Sylvia Sacks**, of New York City, minor child of the late **Herman A. Sacks** of New York"*



...WEDNESDAY MORNING, SEPTEMBER 1, 1920

BUSINESS IN THE ORPHANS' COURT

Guardian Appointed for Minor Child — Several Estates Divided

On motion of Attorneys D. N. Schaeffer & Son, the petition of Mary C. Rorke to sell the property at 936 North 11th street to Frank M. Weiss for $3,150 was approved by Judge Schaeffer in orphans' court. The property belongs to the estate of Joseph B. Rorke, late of Reading, and a bond of $5,000 with George W. Rorke and John H. Rorke as sureties was approved.

Leona F. Sharpless, of Philadelphia, was appointed guardian of Charlotte Ruth Irwin, minor child of George W. Irwin, late of this city, and the guardian's bond of $8,000, with Harry B. and William Irwin, Jr., as sureties, was approved on motion of Attorney John A. Keppelman.

$5,000 Widow's Appraisement

In the estate of Otto A. Doerrman, late of Reading, the widow's appraisement of $5,000 was confirmed absolutely, on motion of Attorney John P. Wanner.

In the estate of Joseph Butterweck, late of Hereford township, the petition of Ambrose L. Benfield, executor of Daniel Benfield, for the discharge of a lien of dower on a tract of land of 73 acres, under the will of Joseph Butterweck, was approved. Attorneys Ira G. Kutz and Joseph R. Dickinson appeared for the petitioner.

The return of the order of sale of real estate in the estate of Benneville Clay was confirmed, on motion of Charles K. Derr. The property, 143 Buttonwood street, was sold to Joseph J. Schmicker for $3,540.

Would Sell Land

Attorney Edward D. Trexler presented to the court the petition of the Berks County Trust Co., guardian of Sherley B. Lacey, a minor, to join with other heirs in the sale of a land in Robeson township, consisting of 112 acres and 65 perches to Haraton Murhon and wife, Mary, for $2,250, and another tract of land of 8 acres and 86 perches, also in Robeson, to William D. Glass and Erma C. Eppenstein for $100, was presented to the court. The minor has a one-thirtieth interest in the two tracts. The bond for the protection of the minor's interests was approved.

On motion of Attorney James B. Baker, the Berks County Trust Co. was appointed trustee for Emma Koch in the estate of Amanda Wagner, late of Tilden township, for uses set forth in the will.

To Partition Real Estate

In the estate of Mary A. Smith, late of Reading, Attorney Joseph R. Dickinson, the petition of John P. and Carl J. Smith for a citation on the other heirs for the partition of real estate left by the decedent was presented. The estate consists of a property at 332 North 10th street.

Jacob E. Walborn was named guardian of Walter H. Geiss, minor son of Ida R. Geiss, late of Reading.

$3,000 For Home

In the estate of Charles F. Reichert, late of Hereford township, the petition of heirs for a private order of sale to dispose of a property, 1315 Walnut street, to Catharine Bausbach, for $3,000, was approved. Attorneys Adam B. Rieser & Son appeared for the petitioners.

Guardians were appointed by the court, as follows: The Berks County Trust Co., for Ruth A. Wagner, minor daughter of Annie L. Wagner, late of Reading; Berks County Trust Co., for Catharine I. M. Schnoke, minor daughter of George Schnode, late of Bethel township; the Colonial Trust Co., for Mary Elizabeth Steinmetz, minor child of Charles M. Steinmetz, late of this city; the Pennsylvania Trust Co., for Edith May Frobey, minor child of James E. Frobey, late of Reading.

The Reading Trust Co. was appointed guardian of Sylvia Sacks, of New York city, minor child of the late Herman A. Sacks, of New York.

Guardian for Children

The Reading Trust Co. was also appointed guardian of Nathan, Gertrude and Bernhard Natelson, minor children of Bessie Natelson, late of New York city. The children have an interest in real estate in this city.

The widow's appraisement of $500 in the estate of William H. Keffer, late of Reading, was confirmed absolutely, as were similar appraisements in the estates of Samuel S. Billman, late of Perry township, and Philip H. Weller, late of Topton.

The widow's appraisement in the estate of Joseph W. Reichert, late of District township, was confirmed nisi, as were appraisements in the estate of Levi L. Becker, late of Centerport, and in the estate of Henry B. Mull, late of Exeter township.

The court confirmed absolutely the widow's appraisement in the estate of J. Daniel Blatt, late of Reading; also the widow's appraisement in the estate of Horace G. Weaver, late of Mt. Penn.

Owner Is in Hospital

The court approved the petition of L. B. Hoyer, guardian, to sell real estate of Anna M. Baumann, a person of alleged unsound mind, who is confined to a hospital at Clarinda, Iowa. The properties are located at 537 Buttonwood street, and 860 North Eighth street, this city.

The return of the order of sale of real estate in the estate of Frederick Huber, late of Reading, was confirmed nisi. A property at 1536 North 9th street was sold to Richard Hopewell for $2,420, and another house at 554 Wunder street was sold to Joseph H. Gilles for $1,850.

Trust Company As Guardian

The Pennsylvania Trust Co. was appointed guardian of Elwood Long, minor son of Daniel W. Long, late of this city. The Pennsylvania Trust Co. also was appointed guardian for Charles Guldin Sheidy, minor child of Charles Sheidy, late of Wernersville; and also appointed guardian of Eleanor M. Machemer, minor daughter of Frank E. Machemer, late of Reading.

On motion of Attorney John B. Rutherford, of Philadelphia, the Pennsylvania Trust Co. was appointed guardian of Emily Claire Lykens, minor child of the late D. Edgar Lykens, late of Philadelphia. The girl now resides in Birdsboro.

HASSLER DIDN'T MEAN TO STEAL THE HORSE

"I only wanted the use of the horse, I didn't intend to steal him," was the unique plea of Louis Hassler before Alderman Oliver M. Wolff, on the charge of horse stealing.

The horse in question was found in Hassler's possession, as he was on his

RECEIVER FOR HOSIERY MILL

Holders of 2,000 Shares in the Standard Company Take Action

Charles T. Davies, of this city, was appointed temporary receiver of the Standard American Hosiery Mills, Inc., of this city, on motion of Attorneys Harry F. Kantner and John B. Stevens, following the filing of a bill of equity by Herman A. Sacks and Joseph A. Sacks, individually, and Herman A. Sacks and Joseph A. Sacks, co-partners, trading as the Daisy Whithead Knitting Co. The plaintiffs allege that the defendant corporation is insolvent.

The bill states that the defendant corporation was organized under the laws of this state and took first the name of Bertha Hosiery Mills of Mohnton, which was later changed to Standard American Hosiery Mills, Inc.

OWN 2,000 SHARES

Herman A. and Joseph A. Sacks, according to the bill, are the holders of 2,000 shares of stock in the defendant corporation. As co-partners in the Daisy Whithead Knitting Mills, they allege, that they are creditors of the defendant corporation to the amount of $56,375, and are guarantors of indebtedness of the corporation to the amount of $29,665.23 and upwards.

The property of the defendant corporation consists of a lot of ground in Mohnton with the building and equipment, and a frame factory building located at Sinking Spring, all of which is valued at $60,000. The other assets of the corporation consist of hosiery finished and in process, and yarns and material valued at $62,516.51.

LIABILITIES OF $143,874

The company has an authorized capital stock of $100,000 divided into 4,000 shares at $25 each. All of the capital stock is issued and outstanding. The liabilities amount to $143,874.56, consisting of mortgages secured upon the real estate, $42,500; amounts payable, $88,190.53,andacceptances and notes payable, $13,184.03.

It is alleged by the plaintiffs that the defendant corporation is insolvent and unable to meet its current indebtedness. They fear that if the creditors press their claims for payment and start proceedings that should enforced sales result the corporation's assets would be disintegrated with loss to the creditors and stockholders.

They also allege that Harry Fisher and Max Fisher, who own 50 per cent. of the stock of the corporation, have opposed all acts of the plaintiff relative to borrowing money to meet the indebtedness of the corporation and have made it impossible to agree upon a business policy. They ask for a receiver to take charge of the property and for an injunction restraining creditors from interfering with the property during the receivership.

Reading Times (Reading, Pennsylvania) • 29 Aug 1922, Tue • Page 3

DEFENDANTS FILE AN ANSWER TO SUIT

In the equity proceedings of Harry Fisher, trading as the Harry Fisher Hosiery mills, against Herman A. Sacks and Joseph A. Sacks, co-partners, trading as the Daisy Whitehead Knitting Co; of New York, the defendants, through Attorney Harry F. Kantner, have filed an answer.

The plaintiff seeks an accounting of the sale of hosiery by the defendants, who according to the bill are his sole selling agents.

In their answer the defendants aver, that there is nothing due or owing by them to the plaintiff on any account whatsoever, and that all proceedings as to the business have been proper. They claim that they were at all times ready and willing to furnish the plaintiff with an account of any or all of their transactions and to give full and complete information as to orders, shipments, charges, etc. They ask that the bill be dismissed.

Sacks-Lewis Wedding.

Miss Esther Lewis, daughter of Mr. and Mrs. Joseph Lewis, of 906 East Eighth street, became the bride of Herman Sacks, son of Mr. and Mrs. S. Sacks, of Manhattan, Sunday night. The ceremony was performed at the Brooklyn Jewish Centre, 667 Eastern parkway, in the presence of 150 guests, by the Rev. Hyman Landau, assisted by Dr. Herbert Goldstein of Institute Synagogue, Manhattan.

Miss Lewis was beautifully attired in a white satin gown trimmed with lace and pearls, and a duchess lace veil. She wore a diamond bracelet, a gift of the groom, and carried a bouquet of roses and lilies of the valley. Her sister, Miriam, attended as maid of honor. The six bridesmaids, gowned in pastel shades, carried old-fashioned bouquets of tulips and sweet peas. They were the Misses Martha Jacobs, Sophie Zazeela, Jean Steinway, Esther Kehrman, Rose Kohn and Bertha Ciechanow. Eleanor Rhoda Linder was the flower girl. Joseph A. Sachs, brother of the bridegroom, served as best man, and the ushers were Jack Lewis, Alexander Lewis, Arthur Newman, Jack Gross, Manuel Swarz and T. H. Tenzer.

A reception followed the ceremony in the dining hall of the Centre, after which the couple departed on an extended honeymoon trip to Florida and Cuba. Upon their return they will make their home at 905 West End avenue, Manhattan.

JUDGE MAY ADDRESSES PAPER BOX MERCHANTS

Gives Interesting Talk Before Manufacturers at Brooklyn Jewish Center

The first step towards the organization of the paper products industry of the Brooklyn Federation of Jewish Charities took place last night at the Brooklyn Jewish Center. Judge Mitchell May addressed a group of the leading men in the paper-box, corrugated paper, and other allied trades in Brooklyn. Herman Brickman, executive director of the Federation, also spoke.

A committee was appointed for the next meeting of the newly formed organization, to draw up a program and prepare a slate of officers. The committee, which will meet Monday, March 8, at the Brooklyn Jewish Center, consists of R. A. Bonime, chairman; Henry Citron, Hyman Freeman, David Freeman, Edward Karfoil, Philip Karlsruher, Samuel Koff, Harry Kovner, Henry Nias, Abraham Price, Julius Reiner, Joseph Rubin, Abraham Cohen, A. Jonas, Louis Weiner, Jacob S. Barshay, Herman Sacks, Jacob Mazer and C. S. Reich.

GOITER CITED IN PLEA FOR ANNULMENT

Herman A. Sacks Says Wife Concealed Malady Until After Marriage.

Herman A. Sacks, a cotton converter, of 905 West End ave., Manhattan, has brought suit in the Supreme Court, Manhattan, for an annulment of his marriage from Mrs. Esther L. Sacks on the ground that she had a goiter and did not tell him at the time of their marriage in Brooklyn, March 15, 1925.

Mrs. Sacks is living with her parents at 906 East Eighth st., Flatbush.

Mrs. Sacks applied today to Supreme Court Justice Lydon for $250 a week alimony and $500 counsel fee, pending the outcome of her husband's suit. Decision was reserved.

Mrs. Sacks, in an affidavit, admits that she has a goiter, but did not know it until it manifested itself in June, 1925. She declared her health has been impaired as the result of one year of married life, and that when she returned from Lakewood, N. J., where she was convalescing last month, to her apartment on West End ave., she found the locks on the door had been changed.

When she was denied admission to her home she was compelled to return to her people. She charges Sacks has not contributed to her support since last February and that he is worth more than half a million dollars.

Sacks, in an affidavit, declared his wife married him for his money and that she has a vivid imagination.

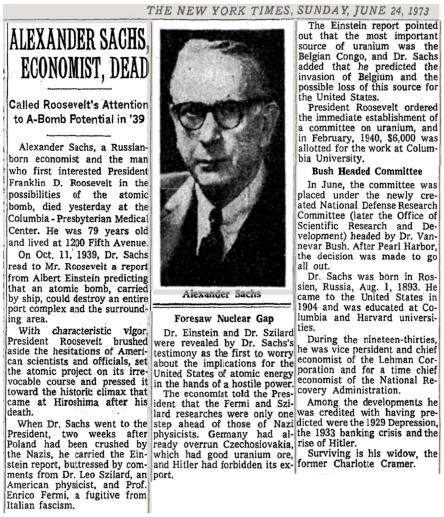
1973 (June 23) - Alexander Sachs (younger brother) dies



THE NEW YORK TIMES, SUNDAY, JUNE 24, 1973

ALEXANDER SACHS, ECONOMIST, DEAD

Called Roosevelt's Attention to A-Bomb Potential in '39

Alexander Sachs, a Russian-born economist and the man who first interested President Franklin D. Roosevelt in the possibilities of the atomic bomb, died yesterday at the Columbia-Presbyterian Medical Center. He was 79 years old and lived at 1200 Fifth Avenue.

On Oct. 11, 1939, Dr. Sachs read to Mr. Roosevelt a report from Albert Einstein predicting that an atomic bomb, carried by ship, could destroy an entire port complex and the surrounding area.

With characteristic vigor, President Roosevelt brushed aside the hesitations of American scientists and officials, set the atomic project on its irrevocable course and pressed it toward the historic climax that came at Hiroshima after his death.

When Dr. Sachs went to the President, two weeks after Poland had been crushed by the Nazis, he carried the Einstein report, buttressed by comments from Dr. Leo Szilard, an American physicist, and Prof. Enrico Fermi, a fugitive from Italian fascism.

Alexander Sachs

Foresaw Nuclear Gap

Dr. Einstein and Dr. Szilard were revealed by Dr. Sachs's testimony as the first to worry about the implications for the United States of atomic energy in the hands of a hostile power.

The economist told the President that the Fermi and Szilard researches were only one step ahead of those of Nazi physicists. Germany had already overrun Czechoslovakia, which had good uranium ore, and Hitler had forbidden its export.

The Einstein report pointed out that the most important source of uranium was the Belgian Congo, and Dr. Sachs added that he predicted the invasion of Belgium and the possible loss of this source for the United States.

President Roosevelt ordered the immediate establishment of a committee on uranium, and in February, 1940, $6,000 was allotted for the work at Columbia University.

Bush Headed Committee

In June, the committee was placed under the newly created National Defense Research Committee (later the Office of Scientific Research and Development) headed by Dr. Vannevar Bush. After Pearl Harbor, the decision was made to go all out.

Dr. Sachs was born in Rossien, Russia, Aug. 1, 1893. He came to the United States in 1904 and was educated at Columbia and Harvard universities.

During the nineteen-thirties, he was vice president and chief economist of the Lehman Corporation and for a time chief economist of the National Recovery Administration.

Among the developments he was credited with having predicted were the 1929 Depression, the 1933 banking crisis and the rise of Hitler.

Surviving is his widow, the former Charlotte Cramer.

Alexander Sachs *(August 1, 1893 – June 23, 1973) was an American economist and banker. In October 1939 he delivered the Einstein–Szilárd letter to President Franklin D. Roosevelt, suggesting that nuclear-fission research ought to be pursued with a view to possibly constructing nuclear weapons, should they prove feasible, in view of the likelihood that Nazi Germany would do so. This led to the initiation of the United States' Manhattan Project.*

Life and career

Born in Rossien, Lithuania, Sachs moved to the U.S. in 1904 to join his brother, ***Joseph A. Sachs****, who was instrumental in his further education. He was educated at Townsend Harris High School in New York City, the City College of New York, and Columbia College. In 1913 he joined the municipal bond department at Boston-based investment bank Lee, Higginson & Co. but in 1915 returned to education as a graduate student in social sciences, philosophy, and jurisprudence at Harvard College. In later life, he was on the faculty at Princeton University.*

Between 1918 and 1921 he was an aide to Justice Louis Brandeis and the Zionist Organization of America on international problems of the Middle East and the World War I peace conference.

From 1922 to 1929 he was economist and investment analyst for Walter Eugene Meyer in equity investment acquisitions. He then organized and became director of Economics Investment Research at the Lehman Corporation, a newly established investment company of Lehman Brothers. In 1931 he joined the board at Lehman. He was vice president from 1936 to 1943, remaining on the board until his death.

In 1933 Sachs served as organizer and chief of the economic research division of the National Recovery Administration. In 1936 he served on the National Policy Committee. ***During the war, he was economic adviser to the Petroleum Industry War Council and special counsel to the director of the Office of Strategic Services.***

He was knighted by the Queen of England and at the time of his death held the title of Sir Alexander Sachs.

He was married to the inventor Charlotte Cramer Sachs (1907–2004) and is survived by, among others, his nephew Paul S. Barr, M.D. of New York; and his nephew Zachary H. Sacks, an attorney in Los Angeles.

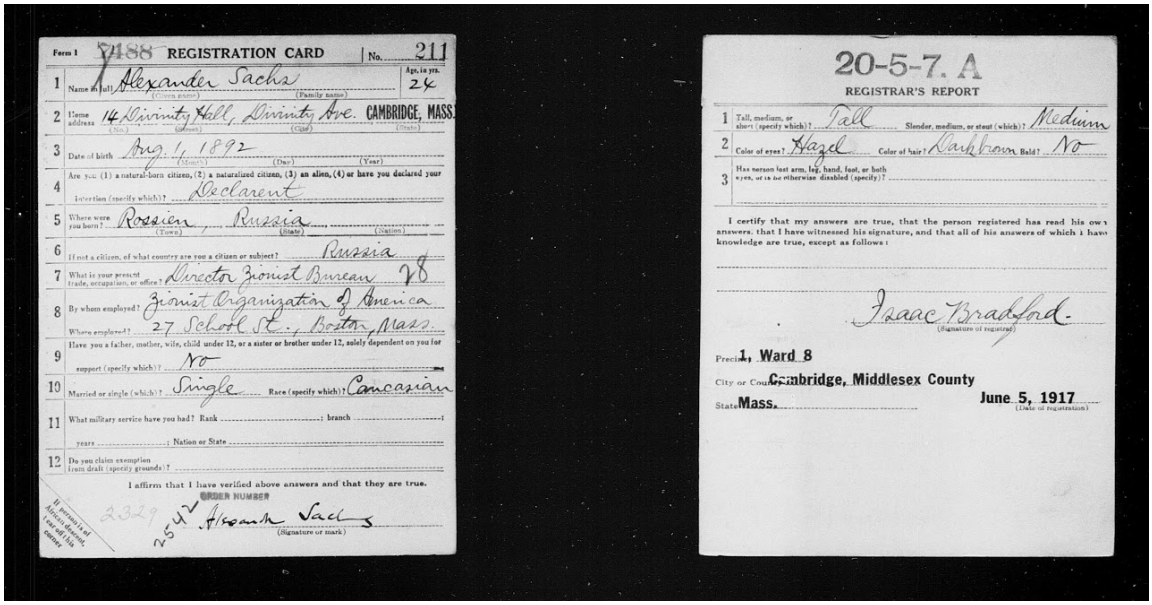
1917 (June 5) - WW1 Registration

Interesting that he signed up for the draft while in Cambridge, Massachusetts - Not while in New York City



Form 1 — 7188 — REGISTRATION CARD — No. 211

1 Name in full: Alexander Sachs (Given name) (Family name) — Age, in yrs.: 24

2 Home address: 14 Divinity Hall, Divinity Ave. CAMBRIDGE, MASS. (No.) (Street) (City) (State)

3 Date of birth: Aug. 1, 1892 (Month) (Day) (Year)

4 Are you (1) a natural-born citizen, (2) a naturalized citizen, (3) an alien, (4) or have you declared your intention (specify which)? Declarent

5 Where were you born? Rossica (Town) Russia (State) (Nation)

6 If not a citizen, of what country are you a citizen or subject? Russia

7 What is your present trade, occupation, or office? Director Zionist Bureau 78

8 By whom employed? Zionist Organization of America
Where employed? 27 School St., Boston, Mass.

9 Have you a father, mother, wife, child under 12, or a sister or brother under 12, solely dependent on you for support (specify which)? No

10 Married or single (which)? Single Race (specify which)? Caucasian

11 What military service have you had? Rank ....; branch ....; years ....; Nation or State ....

12 Do you claim exemption from draft (specify grounds)? ....

I affirm that I have verified above answers and that they are true.

ORDER NUMBER 2329

25 Alexander Sachs (Signature or mark)

If person is of foreign birth, he will also answer

Alexander Sachs claims a restores Palestine Rights the World's Oldest Tragedy

Full page ; [HN00IJ][GDrive]

TAKING JERUSALEM WAR'S FIRST RESULT

Alexander Sachs Claims a Restored Palestine Rights the World's Oldest Tragedy

THE BELGIUM OF HISTORY

Now to Be Restored After Nearly Twenty Centuries of Exile, Deportation and Persecution

At a meeting held in the Ritz-Carlton Hotel last night for the formation of a University Zionist Society in Montreal, Mr. Alexander Sachs, director of the Zionist Bureau for Canada, declared that Great Britain's liberation of the Holy Land along with its declaration of its intention to re-establish Palestine as a national home for the Jewish people, was the one positive fact in the war, and the first chapter in the fulfilment of the British aim in the war. That aim was expressed by the former Premier Asquith, on the 25th of September, 1914, as the enthronement of public right, which, in addition to the repudiation of militarism, meant that room must be found and kept for the independent existence and the free development of the smaller nationalities, each with a corporate consciousness of its own. British arms and British statesmanship had thus enthroned the idea of public right in the oldest and most radiant corner of civilization—Palestine.

"There is magnificent historic justice in this," said the speaker. "The peace of Europe was broken by the violation on the part of Germany of the European covenant, with a small nation—Belgium. The new covenant which shall make possible peace and progress of all the nations is beginning by a new covenant with the Belgium of history, a nation conquered by the scientific militarism of Rome, a people deported and persecuted from land to land, and from age to age, yet surviving its conquerors and oppressors and living to see the fulfillment of its aspiration for its national land, at that critical point of civilization, when the great powers are allied to resist another Rome and another scientific militarism."

The speaker pointed out that Belgium bore the same relation to the three powers in Europe. England, France and Germany, that Palestine had to the three continents, Europe, Asia and Africa. Belgium had been called "the cross-roads of Europe." Palestine has the bridge of the three continents, and between the maritime basin of the Mediterranean and that of the Indian Ocean, Belgium was a buffer state just as Palestine would be. Three years and three months after Great Britain entered the war to vindicate the "Cross-roads of Europe," she conquered the "Cross-roads of the three continents," in the same great cause.

"The declaration of the Right Hon. Arthur J. Balfour, secretary for foreign affairs, 'His Majesty's Government views, with favor, the establishment in Palestine of a national home for the Jewish pepople and will use its best endeavors to facilitate the achievement of this object,' that declaration," said the speaker, "made to the tune of the triumphal entry of the British army, brings about the healing of the oldest and most persistent national tragedy in history. It is an earnest of the healing of the national tragedy which opened the war, and, above all, an earnest of the healing of the nations which allied victory would bring about."

The speaker told of the great results already attained in Palestine by Jewish colonists, and said it would be a great encouragement to the inhabitants of the plains of Northern France and Belgium when, after peace they once more attempted to reconstruct their countries.

A committee was formed to consider the whole basis and purposes of a University Zionist Society in Montreal, and their report will be made to another meeting. Mr. Louis Fitch presided last night.

MASS FOR SOLDIERS

Requiem Service at Chapel of Notre Dame de Bon Secours

A requiem mass was celebrated at 8.30 yesterday morning at the Chapel of Notre Dame de Bon Secours, for the repose of the souls of the French soldiers from Canada who had fallen on the field of honor in the war.

A large number of the French Army Sac au Dos, 1914, under Captain Raoul Vennat, attended the service. The French Consul-General, M. C. E. Bonin, was also present with members of his staff, and Capt. Dutoit, with other French officers who are in Montreal on a special mission. The Military Headquarters were represented by Major-General E. W. Wilson, C.M.G., G.O.C., Lt.-Col. Hill, G.S.O., Lt.-Col. W. J. Stewart and Lt.-Col. L. LeDuc, while there was a large attendance of other officers and men from the C.E.F. and the Active Militia.

The Terrible Toil,

Conditions and Prospects in Palestine

By ALEXANDER SACHS

Assistant to Executive Secretary of the Zionist Organization of America

FROM the outbreak of the war until the British occupation Jewish colonization passed through a critical period. The three and a half years seemed like one day of suffering. The crisis appeared in two forms: economic want and political oppression. The economic situation was affected by the moratorium; by interruption of communication and exchange between Palestine and the outside world; by enormous depreciation of Turkish paper money; by abnormal taxation and official robbery, and by the plague of locusts in 1915. Of political oppression three periods may be named: First, the regime of Bey-Adin, Kaimakam of Jaffa, a zealous anti-Zionist, under whom sentences of exile were passed and the evacuation of Jaffa was ordered; second, the regime of Chassan Bey who instituted indescribable persecution, plunder, anarchy, false accusations and tyranny, and at this time cholera and spotted fever broke out; third, from the evacuation of Jaffa until the British occupation, the days of panic and despair, impression of men into the Turkish army, arrest and exile of innocents, incredible sufferings—and then deliverance came.

The Zionist Commission appointed by the British Government and the Zionist Organization, immediately upon its arrival in Palestine, in April, 1918, set up a relief department, "to coordinate the relief work in Palestine." The Relief Department has now a branch at Cairo and the following agencies in Palestine:

1. In Jerusalem, relief is under the immediate supervision and control of a special Administrative Committee of the Commission.

2. In Jaffa, the administration of relief is in the hands of the Va'ad Ha'ir (Committee of the City) acting with Mr. M. J. Rosenhack, representing the Relief Department.

3. In the Judean Colonies, such relief as is necessary is administered by the Va'ad of each colony, aided by the Va'ad Haitachaduth (Committee of the Federation of Jewish Colonies).

JERUSALEM

The Jewish population of Jerusalem is now 26,000. In the last few years of the war, the Jewish population has been reduced from 56,000 to 26,000. The war has similarly swept away sources of income as well as of life, and the condition was aggravated by a depreciation of Turkish paper money. Jerusalem has also suffered during the war from the partial activity to which the best elements of the Jewish life were restricted under the Turkish regime, and from the imprisonment and exile of many of its most prominent and valuable workers. Finally came disease. Malaria is a constant, though a remediable illness in the town: some 60 per cent. of the inhabitants

[HP005T][GDrive]
page 604 ... (625 in PDF)

show signs of malarial infection. This population without bread-earning occupations, without food and clothing, deprived of many of its best protectors, was ravaged by severe epidemics.

The work of the Jerusalem Relief Department consists of distribution of bread to school children, orphans, and inmates of the institutions, medical relief, and the support of hospitals and institutions. For relief purposes, Hebron counts as a branch of Jerusalem. The funds for the relief come from the American Jewish Relief Committee, supported by direct relief to individuals and institutions sent through the Zionist Organization. Vast sums in the hundreds of thousands were and are required to meet the situation.

Constructive relief work is being conducted through Ateliers for Women and Girls, which are also playing a most important part in the education of the city. They consist of needle work, school and lace, and wool ateliers employing around seven hundred women and girls, and while a considerable amount is given as subvention, they are gradually becoming self-supporting. The Bezalel School of Arts and Crafts and Workshop, are also employing workers. This institute of Applied Arts is mainly in need of material to carry on its work.

Of the special problems confronting Jerusalem, important place should be given to the problem of the orphans, of whom, it is estimated, there are 2,500, a number representing 10 per cent. of the population. The Commission's constructive plan is to distribute them among the agricultural colonists and to provide from the central sources for relief, for their maintenance and education.

JAFFA

Before the evacuation of the Jewish population by the Turks, the Va'ad Ha'ir had a complete relief organization, including in relief the sale of food at cost price and provision for orphans and aged. Since the return of the Jewish population to Jaffa, the Va'ad is carrying on the existing relief work in opening institutions, chief among them, Jaffa Jewish Hospitals which has involved originally an expenditure of £5,000.

JUDEAN COLONIES

As to the problem of relief in the Colonies, the Relief Department has granted the Va'ad Haitachaduth money for relief during June, after which it was intended to arrange for relief in food. A further sum was given the Va'ad for the purpose of small loans to inhabitants of the colonies who do not own land.

There is a greater relief problem affecting the laborers and traders.

General Allenby's victorious march has also liberated Galilee and Samaria, so that relief work, especially food control, has been opened there under direction of the Union of Galilean Colonies. In Safed alone there are 500 orphans whose parents have died during the war.

LOOKING FORWARD

A correspondent writes of the recent visit paid by five members of the Zionist Commission to some of the colonies in occupied territory showing that the colonists have got the

PALESTINE VICTORY IS LIGHT IN GLOOM

Alexander Sachs Told Canadian Club Importance of Near East Front

JEWS OF WORLD PLEASED

Grateful To Great Britain For Declaration in Favor of Zionist Movement—Isaiah's Foreign Policy

In the redemption of Palestine, and the return of the Jews to the land of which they were dispossessed so many centuries ago, Mr. Alexander Sachs told the Canadian Club in the Windsor Hotel yesterday there was an earnest of a new era for all peoples in the whole world as soon as the German scheme for a Berlin-Bagdad railway and domination of the world has been defeated. He believes Palestine to be the great strategic point in the future life of the world, being, as it is, the cross-roads of three continents, the natural meeting point for transcontinental lines from Pekin to Paris, from India to Petrograd and to other places. He believes that if the Jews hold Palestine under the suzerainty of the British Government, there will come a time when people of Australia can travel to England in fifteen days for an Imperial conference, and men in India get to London in three days. The alternative is for Germany to win and the despotic Turk to unite the Eastern countries and those parts of Russia in Europe and Asia, where Mohammedanism predominates into one Empire under a government which would revive the worst features of the Dark Ages.

Mr. Sachs protested against the idea that the eastern front is a side-show. The front had to be considered as a whole, and the importance of the east was to be seen in the German willingness to compromise in the west and not in the east. So, though the sky was dark temporarily in the west, the gloom was partially dispersed by the light coming from the east. The British successes on the Jordan were real successes. That front was important, because the safety and security of the British Empire were bound up in securing this highway between the east and the west. At the very beginning, Lord Kitchener's plan had been to attack the Germans through Turkey and not through the Dardanelles in order to prevent the Turks becoming an important military factor, and thus bring the whole Bagdad scheme to naught.

ISAIAH'S PROPHECY.

The speaker contended that Isaiah, the great Hebrew prophet, had preached tens of centuries ago that the foreign policy of a nation should be moral and not rapacious. Asquith and Lloyd George's utterances during this war had been exactly the same. It was necessary to make granaries of Palestine and Mesopotamia as well, to prevent the famine after the war which Mr. Hoover feared. The discovery by Aronstein, a Jew, in the Mt. Carmel agricultural experiment station, of wild wheat, was an important discovery. It had been introduced into Montana and Arizona because wild wheat would grow anywhere.

Mr. Sachs traced the history of the Jew in his migrations, which were really deportations, the reasons for his stubborn survival, his contributions to history, and progress in one country after another, Hannibal, the Carthaginian general, being a Jew, as his name attested. The declaration of November 22nd, 1917, by the British Parliament, had at length brought in sight of the Jewish people, the eternal Belgium of history, their promised land. The speaker told of the splendid productivity of the soil of Palestine, the plans of Jews for its development, with the support of Great Britain, the things already accomplished, the dreams for the future, and the great gratitude of Jews in every country for Great Britain's guarantee. The Jews had a mixture of poetry and practicality in their natures, just as had the British, who were a nation of shop-keepers as well as of Shakespeares. The British were a real Zionist people, a Bible people, and they were taking the role of the Annointed One prophesied by Hebrew prophets to act as restorer of the Jews to their land. Empires were needed for security and small nations for intensive effort. Small trees produced most fruit and it was the ambition of Palestine to be one of those small trees.

Mr. W. M. Birks, president, introduced the speaker.

THE CALGARY DAILY HERALD, TUESDAY, JUNE 18, 1918 9

ALEXANDER SACHS

Director of Canadian Zionist Bureau, Who Is Here Today

ALEXANDER SACHS LECTURES TONIGHT ON ZIONIST AIMS

Distinguished Jewish Scholar Will be Heard Tonight in Paget Hall

Alexander Sachs, M.A., director of the Zionist Bureau for Canada, is a visitor to Calgary today, and tonight will deliver an address in the Paget Hall. He has come here to tell an interesting story of the new Zion which has been established by the British people.

In the course of an interview this morning, Mr. Sachs, who is an eloquent lecturer, stated that in November last the British government declared in its famous statement that had stirred the world and thrilled the hearts of Britishers as well as Jews that it favored the establishment in Palestine of a national home for the Jewish people and that it would use its best endeavors to facilitate the achievement of this object.

Authorized Commission

Since then, stated Mr. Sachs, Jerusalem has been captured by the Allies and the whole of southern Palestine. In furtherance of this declaration, the British government has authorized the sending of a Zionist commission, whose head is Dr. Chaim Weizman, the famous inventor of explosives used on the western front.

This commission has as its purpose the rehabilitation of the Jewish colony and to prepare for the final establishment of the Jewish national home in Palestine. It will lay the foundation of a Hebrew university, the site of which has already been acquired on the Mount of Olives, looking out upon the Holy City and "radiating its light and attracting its forces from the world."

Headquarters Now Open

Its provisional Jewish government has opened its headquarters in the Jewish garden city of Tel-Aviv, the "Hill of Spring." British officers and soldiers have already found this to be an active centre of practical as well as spiritual work, said Mr. Sachs.

This dream of rehabilitation, said the visitor, has been going on for the past 30 years and much sacrifice has been made by Jewish pioneers.

It is interesting to state that Mr. Sachs is shortly leaving for overseas as a combatant soldier in the Jewish Legion which was formed in England some considerable time ago.

Twelve THE JEWISH MONITOR Friday, December 5, 1919.

ZIONISTS PRESENTED GIFT TO PRINCE OF WALES.

H. R. H. The Prince of Wales received on board the Renown at 10 o'clock Saturday morning a deputation consisted of Judge Julian W. Mack, president; Dr. Stephen S. Wise, vice president; Mr. Jacob de Haas, executive secretary, and Alexander Sachs, assistant executive secretary of the organization.

The deputation presented to H. R. H. The Prince of Wales a silver menorah studded with garnets in appreciation of the official declaration by the British government on November 2nd, 1917, in favor of the establishment in Palestine of a National Home for the Jewish people. The Menorah which the Zionists presented is particularly appropriate. It is one of the first pieces of work turned out by the Bezalel School of Arts and Crafts in Jerusalem after its liberation by General Allenby two years ago, during the Chanuka festival.

In presenting this gift, Judge Mack said:

"Your Royal Highness: We have the great honor to offer you the greetings of the Zionist Organization of America, a large and representative body of American Jews. The mighty British Commonwealth of which your most honored father is the sovereign head has stood out for some centuries as the friend and protector of the Jewish people, a furtherance resting in part upon British devotion to the moral and spiritual ideals of the ancient Jewish commonwealth and in part upon the traditional British championship of the rights of smaller peoples.

Jews in our land and in all Allied lands were inexpressibly gladdened by the Balfour Declaration of November, 1917, affirming the purpose of the British government to facilitate the creation in Palestine of a National Jewish Homeland. This declaration was shortly thereafter sealed by the deliverance of Judeau from the yoke of Turkish misrule by the British armies under Sir Edmond Allenby, which included some of the bravest of young British Jews as well as the Jewish Legion drawn in part from the Jewish youth of our own land.

Under the rule of your most honored father, the British Empire has thus by the Balfour Declaration kindled the light of hope for multitudes of our people that walk in darkness. We have therefore ventured to believe that your Royal Highness might be pleased to receive at our hands, speaking on behalf of the Zionist Organization of America under the honoring leadership of Justice Louis D. Brandeis of the United States Supreme Court, this Hebrew symbol of light and hope, the Menorah, the first work of the Jewish craftsmen of Jerusalem after its redemption by Britain.

May this symbol ever token the gratitude of the people of Israel to your Commonwealth and above all Israel's deep and unfeigned devotion to your father's house, for your own is the thrice royal and blessed lineage that does justice, loves mercy and walks humbly before God.

AMERICAN ZIONISTS ISSUE STATEMENT

Serious Allegations Against Dr. Weizman and the Leaders of the World Organization

THE Jewish Exponent is in receipt of a pamphlet of 125 closely printed pages, containing a detailed statement issued by the American Zionist leaders who have seceded from the Zionist World Organization, concerning the causes which led them to take the course they decided upon. This statement has been prepared for circulation among the delegates at the Congress which is to be held next month in Carlsbad.

With the statement are issued a number of "exhibits" or appendices, the text of several of which has already appeared in the Jewish Exponent. They are, however, not essential to a full comprehension of the case which the American Zionist leaders present in justification of their action. The statement in its introductory paragraphs says:

"On June 6, 1921, the annual convention of the Zionist Organization of America, under the influence of Dr. Weizmann, Mr. Ussischkin, Dr. Schmarya Levin and their colleagues, refused to approve the report of its officers. As a result, Mr. Justice Brandeis, honorary president; Dr. Stephen S. Wise, honorary vice president; Judge Julian W. Mack, president; Dr. Harry Friedenwald and the Hon. Nathan Straus, vice presidents, and thirty-three of their associates on the National Executive Committee resigned and announced that in the circumstances they could not accept any office in the Zionist Organization of America.

"Later other members of the Executive declared themselves likewise in sympathy with Judge Mack's leadership, making a total of 36 out of the 52 members. Their names follow:

Maurice L. Avner, Oscar Berman, Israel B. Brodie, Jacob de Haas, Benjamin V. Cohen, Mrs. Mary Fels, Max J. Finkelstein, Bernard Flexner, Prof. Felix Frankfurter, Dr. Harry Friedenwald, Nathan E. Goldstein, Dr. George Gordon, Max L. Grant, Rabbi Dr. Max Heller, Rabbi J. D. Jurman, Prof. Dr. Horace M. Kallen, Nathan D. Kaplan, Henry H. Levenson, I. Irving Lipsitch, Judge Julian W. Mack, Emanuel N. Mohl, Judge Hugo Pam, S. Rittenberg, Sol S. Rosenbloom, Jonas Rosenfeld, Jerome J. Rothschild, I. Rude, Rabbi Dr. Samuel Sale, William Sauber, S. Shapinsky, Rabbi A. H. Silver, D. W. Simons, Hon. Nathan Straus, Robert Szold, Samuel H. Waldstein, Rabbi Dr. Stephen S. Wise.

"Concurrently, Mr. Justice Brandeis resigned as honorary president of the World Zionist Organization, and Judge Mack, Dr. Wise, Dr. Friedenwald, Mr. de Haas, Mrs. Fels and Prof. Frankfurter resigned from the Greater Actions Committee. The following of the staff of the Zionist Organization of America also resigned: Reuben Horchow, assistant treasurer and secretary to the Executive Committee; Alexander Sachs, Adolph Hubbard, A. H. Fromenson.

"We resigned office; we did not resign our Zionism. Some of us had been active in the cause even before the first Congress. Zionists we were; Zion-

Perhaps we were at fault in not laying the facts before the Zionist world sooner. We refrained from making them public, even though our leadership and the integrity of the American Organization were involved, because we hoped and hoped and hoped that we might induce the European leaders to abandon principles false to the movement and to adopt practices making co-operation possible. But Dr. Weizmann and his associates willed that there be no peace; they came to America not to confer, but to conquer."

Then follows a detailed account of the differences which led to the action taken at the Cleveland Zionist Conference. Practically all of this matter, in its essentials, has been published in the columns of the Jewish Exponent from time to time.

The statement concludes as follows:

"It is our hope that out of the clash of conflicting ideas and purposes which has produced the present crisis in Zionist affairs, our one common purpose may emerge in a clearer light. Once the philosophy of power is abandoned, we confidently hope, that through the voluntary co-operation of all its constituent parts, the world movement will be revitalized and its executive organ strengthened for their true and important tasks. We hope that when the struggle is over and the crisis past, the way will have been found for the free and whole-hearted co-operation of all Jewry in our common cause.

"On behalf of the former administration of the Zionist Organization of America.

"JULIAN W. MACK,
"STEPHEN S. WISE,
"DR. HARRY FRIEDENWALD,
"NATHAN STRAUS,
"FELIX FRANKFURTER,
"MARY FELS,
"JACOB de HAAS,
"ROBERT SZOLD."

The contents of the pamphlet are as follows:

gravity of the step taken. We took it because we should be false to the cause if we did not dissociate ourselves from the course of conduct pursued by those who now assume to direct the movement.

"Seeds of misinformation and misrepresentation have been widely sown as to the facts which compelled our action. Garbled accounts and partisan reports have been spread broadcast. It is necessary that the Zionists of the world should know the truth. That what we have to say will reflect upon some of those who in years have labored for the Zionist cause, we regret. But gratitude for the past, respect for those who served well in the past, must not deter us from facing the duties of today and from insisting upon the maintenance of the high standards indispensable to attainment of our noble ends. We therefore submit the facts to the candid judgments of our fellow Zionists.

The DAILY WASHINGTON MERRY-GO-ROUND

By DREW PEARSON and ROBERT S. ALLEN

SPRAGUE'S OWN INSIDE STORY OF HOW HE GAVE RESIGNATION TO F. D. R.; PROFESSOR DAZED IN SPOTLIGHT GLARE DELUGED BY COMMERCIAL OFFERS; GENERAL JOHNSON FINDS HE HAS A MYSTERY MAN IN DR. ALEXANDER SACHS

throughout the nation.

MYSTERY MAN

Gen. Hugh Johnson has gone the president's forgotten man one better. He has a mystery man.

Several months ago Dr. Alexander Sachs, brilliant, witty head of the NRA research division, suddenly disappeared from his office. The whisper went that despite a personal plea of the president, Sachs' employers, the New York banking firm of Lehman & Brothers, had commanded Sachs' return.

NRA spokesmen emphatically denied that Sachs had resigned, explained that he had merely taken a rest trip to Bermuda, pointed to the fact his name was still on his office door.

The sign is still there. So is Sachs' office staff. But not Sachs. Twice recently he has been in Washington, on one occasion used a stenographer from his office. But Johnson, despite repeated effort, has not been able to contact him.

FDR CALLS PARLEY ON POWER POOLING

WHITE HOUSE CHARGES NEWSPAPER WITH POLITICAL PLOT

ELECTRICITY AT CHEAPER RATES IS AIM OF PRESIDENT

Representatives of Private Utilities, Banking and Electric Equipment Industries To Meet At Washington Sept. 30.

By DOUGLAS B. CORNELL.

Washington, Sept. 19 (AP)—A conference to explore the possibility of providing cheap electricity by pooling public and private power in the Southeast and, ultimately, in other regions was called today by President Roosevelt for September 30.

In a statement summoning the meeting of federal power officials and representatives of private utilities, banking and electric equipment industries, the president said:

"The public interest demands that the power that is being or soon will be generated by the Tennessee Valley Authority and at the Bonneville dam and other public works projects should be made to serve the greatest number of our people at the lowest cost and, as far as possible, without injury to existing actual investment."

To Aid Rural Program

It appears, Mr. Roosevelt added, that pooling of power through the joint use of existing transmission line networks "will smooth out the peaks and valleys of separate system operations, reduce the amount of necessary reserve capacity and postpone the need for investment in new generating facilities."

A regional net work, he said, also would promote rapid expansion of the government's rural electrification program.

It was explained at the White House that the conference was being called for September 30 because existing contracts between the Commonwealth and Southern corporation and the Tennessee Valley Authority for interchange of power and common use of transmission facilities soon will expire. Their present arrangement was described as a rudimentary form of pooling.

The confeernce was announced soon after Mr. Roosevelt returned to Washington this morning from Cambridge, Mass., to be with Mrs. Roosevelt, who is ill of grippe. He expected to leave tomorrow or Monday night for his Hyde Park, N. Y., home, taking Mrs. Roosevelt with him. White House assistants said her condition was improving steadily.

Invited to Parley

Those invited to the power conference were: Wendell L. Willkie, president, Commonwealth and

(Continued on Page 3, Section 1)

Southern corporation; Preston S. Arkwright, president, Georgia Power company; Samuel Ferguson, chairman of the board, Hartford Electric Light company; Owen D. Young, chairman of the board, General Electric company; Russell C. Leffingwell of J. P. Morgan and company; Arthur E. Morgan, chairman, and H. A. Morgan and David E. Lilienthal of the Tennessee Valley Authority; Frank R. McNinch, chairman, and Basil Manly of the Federal Power commission; Frederic A. Delano, vice chairman of the National Resources committee; Morris L. Cooke, Rural Electrification administrator; Louis B. Wehle, New York attorney, and Alexander Sachs, research director of Lehman corporation.

[HN00IV][GDrive]

1936 (Sep 30)

https://www.loc.gov/item/2016878596/

"President discusses power pool, Washington, D.C., Sept. 30. President Roosevelt discussed the question of pooling private and public electric power with private and government power experts at the White House today. After a conference that lasted most of the afternoon Frank R. McNinch, Chairman, Federal Power Commission, and Wendell L. Wilkie, President of Commonwealth and Southern Corporation, emerged from the President's office to state that President Roosevelt had agreed to consider pooling Government hydroelectric projects and private power facilities in the TVA area. The president's decision will not only mean an exchange between the Tennessee Valley Authority and private utilities of the Southeast but touch possibilities for Bonneville Dam on the Columbia River and other public works projects. Harris and Ewing, Alexander Sachs, extreme right"

The Washington Merry-go-Round

By DREW PEARSON and ROBERT S. ALLEN

WASHINGTON.—The old power keg, the power issue, is sizzling within the New Deal again, and may break out into the open at any moment.

This time it is going to be a congressional fight like the holding corporation bill row, but a war involving such important projects as the Tennessee Valley authority.

Chief issue at stake is whether the New Deal should compromise with the power companies.

Liberals inside the administration say Roosevelt's overwhelming election is a passport to the president to push the power fight to the limit. They want no compromise.

Pseudo-liberals and conservatives say the president should now work out a system whereby the government and private power companies can cooperate. They propose the British "grid" system, or power pool, by which the generating and transmitting equipment of both public and private is consolidated into a single network, operated by a joint board on which the public and private power companies are both represented.

Object of the grid system is to eliminate costly competition between private and public projects.

Cast of Characters

A weird cast of characters is taking part in this controversy.

Those advocating the grid system or power pool are' Louis Brandeis Wehle, nephew of Justice Brandeis, and a Harvard classmate of the president's; now a New York lawyer for Prudential Life and other firms with investments in power

Alexander Sachs, rotund, genial economist for the Leham Corp., banking firm; also General Johnson's first economic adviser in NRA.

Basil Manly, pseudo-liberal vice-chairman of the federal power commission:

Dr. Arthur E. Morgan, crotchety, hard-working chairman of TVA.

Chief opponents of the power pool are:

David E. Lilienthal, sleek, black-haired, crusading director of TVA:

J. D. Ross, lethargic, idealistic member of the securities-exchange commission, and former superintendent of the Seattle power system, largest and most successful municipal plant in the country.

The Row

During the campaign the above held a conference at the white house when a plan for pooling Tenessee Valley power operations was discussed. Sachs and Brandeis' nephew, both representing investment companies with money tied up in the power companies, urged the pool system.

Ross and Lilienthal, their dander up, warned the president that the plan was a utility-concocted scheme to out-bargain the government at the very moment the latter had the power companies on the run. They claimed that in such a pooling system, the government was bound to lose out to the private companies.

The president, at that time, was non-committal. He postponed any decision until after elections.

Renewed Fight

But just as he sailed for South America, the issue cropped up again.

It arose as a result of increasing friction between Dave Lilienthal and A. E. Morgan, both executives of TVA. The two men have been getting on each other's nerves. Last spring Morgan served notice on the white house that if Lilienthal were reappointed (his term was up in June), he, Morgan, would resign.

Roosevelt serently reappointed Lilienthal. Morgan did not resign. Now it begins to look as if the president hoped that he would. In fact, when the president returns, Morgan's retirement would not surprise inner white house advisers.

Long Shot

Shortly after the election Colonel Robert McCormick, publisher of the violently anti-New Deal Chicago Tribune, instructed his Washington bureau to obtain a color portarit of the president for the Tribune's Sunday rotogravure section..

With some misgivings, one of the Tribune's correspondents submitted the request to white house secretary Steve Early.

"If it were for you personally," Early, a one-time reporter, replied, "we'd be glad to oblige. But there are no favors being extended here to Mr. McCormick."

That, apparently, closed the matter. The Tribune reporter departed —but he did not give up.

The day the president sailed for the Pan-American peace conference, the president and his white house staff posed with newspapermen at a press conference picture. In addition to the official photographer several other camermen from Washington newspapers were permitted to "shoot" the picture.

Unknown to the white house, one of them was equipped with a color-camera, and he "shot" the president for the Chicago Tribune.

Merry-Go-Round

What's in a name? Chief legal officer of the treasury's procurement division is William K. Laws; two budget bureau officials are J. J. Love, Jr., and W .S. Stork; and the secretary to the assistant disbursing officer is Mrs. M. G. America. . . . Slated for early return in a high New Deal post is able, popular Frank Walker, former head of the national emergency council. Walker resigned last year because of the demands of his extensive moving picture theatre business, but his private afairs are now in shape so that he can leave them. . .. Donald S. Thompson, acting chief of the research division of the Federal Deposit Insurance corporation, has figured out this interesting statistical comparison: President Roosevelt captured 98.5 percent of the electorial college vote; approximately 98.5 percent of all bank depositors are protected by the government's deposit insurance.

BEHIND THE SCENES IN WASHINGTON

By Rodney Dutcher

Secret Battle Going On Over Whether Securities Commission Shall Protect Investers or Bankers . . . Robinson Appointment to Court Will Bring Battle for Senate Majority Leadership.

By RODNEY DUTCHER
Kenosha Evening News Washington Correspondent

Washington—The question whether the Securities Exchange Commission should emphasize a desire to "be fair to the brokers and bankers" or a determination to "protect the investor" has again become an issue, following resignation of Chairman James M. Landis.

Crusaders for adequate regulation and for enforcement of the securities act, claiming that the New Deal has provided neither, insist that Roosevelt's decision will tell whether the administration really means its frequently reiterated promises to protect security holders.

Commissioner William O. Douglas is out in front as the most likely successor to Landis, But if the professional manipulators of what Justice Brandeis used to call "other people's money" have anything to do with it, Douglas won't get the job.

Says Investors Gypped

Douglas is an able lawyer and an expert on corporation law. When he was at Yale he was said to be one of the highest paid law professors in the United States. He has had experience in the securities business.

He handled one of the SEC's outstanding jobs—an investigation of corporate reorganizations and the work of protective committees, with a report and a legislative plan submitted to Congress. He demonstrated his fearlessness in a speech to the Bond club during which he told New York bankers that investors were being gypped by financial concerns which reaped commissions on stock and bond flotations far in excess of the value of their services.

Douglas boldly declared in favor of competitive bidding for the privilege of handling new issues, as against the traditional Wall Street custom, which he said often enabled certain banking houses to monopolize such business. He charged that fees were being exacted for underwriting when there was no need for it, and predicted that bankers would lose their financial power over such processes as management, formulation of industrial policies and reorganizations.

Wall Street didn't like it at all. And its emissaries, as Douglas presumably must have anticipated, have been pulling all possible wires here to see to it that Douglas doesn't succeed Landis. Large contributors to the Democratic campaign fund have joined in the stop-Douglas movement. Dr. Alexander Sachs of Lehman Brothers has been reportedly working for appointment of a "safe" chairman. Although the purpose of the securities act is to regulate bankers and brokers and to protect the investor, it is being seriously proposed that the commission ought to have one or two brokers among its members.

Investors may well watch as closely as they can the progress of this behind-the-scenes battle. The appointment of SEC's next chairman will shed some light as to the integrity of the New Deal.

Battle For Leadership

If Senator Joe Robinson of Arkansas goes on the Supreme Court, the fight for the very important post of majority leader in the Senate is expected to be between Senator Alben Barkley of Kentucky and Senator James F. Byrnes of South Carolina. (Don't ignore the "if.")

Barkley would be the administration candidate for the job. He is liberal without being radical, and comes from a state which is far enough north and far enough south to figure as a softening factor in the troublesome sectional problem in Congress. He gets along well with all factions and has qualities of leadership.

Byrnes also is popular, but not so much with liberals as with conservatives. Although his ability is obvious and his relationships with Roosevelt have been close in the past, the White House hasn't forgiven him for seeking an amendment to the Guffey coal act which would have forced the President to sign—or reject—an unqualified condemnation of sit-down strikes.

Byrnes is out after the powerful position. So, presumably, is Barkley, although less obviously. As soon as Justice Van Devanter resigned, Byrnes became the busiest promoter in the Senate for the Supreme Court aspirations of Robinson.

It is rather vital to the President to have a Senate leader of unquestioned loyalty. Consequently, if Senate Democrats should choose Byrnes in preference to Barkley, it would mean that the current Senate revolt against the White House direction had gone far into the dangerous stage.

1939 (Oct) - The Atomic Bomb proposal / letter

Atomic bomb proposal letter story (from Wikipedia / Robert Jungk)

Saved version of Alexander Sachs : [HK000X][GDrive]

Robert Jungk (See https://en.wikipedia.org/wiki/Robert_Jungk) describes Sachs's role in bringing to President Roosevelt's attention the possibility of an atomic bomb:

It was nearly ten weeks before Alexander Sachs at last found an opportunity, on October 11, 1939, to hand President Roosevelt, in person, the letter composed by [Leo] Szilard and signed by [Albert] Einstein at the beginning of August [1939]. In order to ensure that the President should thoroughly appreciate the contents of the document and not lay it aside with a heap of other papers awaiting attention, Sachs read to him, in addition to the message and an appended memorandum by Szilard, a further much more comprehensive statement by himself. The effect of these communications was by no means so overpowering as Sachs had expected. Roosevelt, wearied by the prolonged effort of listening to his visitor, made an attempt to disengage himself from the whole affair. He told the disappointed reader that he found it all very interesting but considered government intervention to be premature at this stage.

Sachs, however, was able, as he took his leave, to extort from the President the consolation of an invitation to breakfast the following morning. "That night I didn't sleep a wink," Sachs remembers. "I was staying at the Carlton Hotel [two blocks north of the White House]. I paced restlessly to and fro in my room or tried to sleep sitting in a chair. There was a small park quite close to the hotel. Three or four times, I believe, between eleven in the evening and seven in the morning, I left the hotel, to the porter's amazement, and went across to the park. There I sat on a bench and meditated. What could I say to get the President on our side in this affair, which was already beginning to look practically hopeless? Quite suddenly, like an inspiration, the right idea came to me. I returned to the hotel, took a shower and shortly afterwards called once more at the White House."

Roosevelt was sitting alone at the breakfast table, in his wheel chair, when Sachs entered the room. The President inquired in an ironical tone:

"What bright idea have you got now? How much time would you like to explain it?"

Dr. Sachs says he replied that he would not take long.

"All I want to do is to tell you a story. During the Napoleonic wars a young American inventor came to the French Emperor and offered to build a fleet of steamships with the help of which Napoleon could, in spite of the uncertain weather, land in England. Ships without sails? This seemed to the great Corsican so impossible that he sent [Robert] Fulton away. In the opinion of the English historian Lord Acton, this is an example of how England was saved by the shortsightedness of an adversary. Had Napoleon shown more imagination and humility at that time, the history of the nineteenth century would have taken a very different course."

After Sachs finished speaking the President remained silent for several minutes. Then he wrote something on a scrap of paper and handed it to the servant who had been waiting at table. The latter soon returned with a parcel which, at Roosevelt's order, he began slowly to unwrap. It contained a bottle of old French brandy of Napoleon's time, which the Roosevelt family had possessed for many years. The President, still maintaining a significant silence, told the man to fill two glasses. Then he raised his own, nodded to Sachs and drank to him.

Next he remarked: "Alex, what you are after is to see that the Nazis don't blow us up?"

"Precisely."

It was only then that Roosevelt called in his attaché, [Brigadier] General [Edwin] "Pa" Watson, and addressed him—pointing to the documents Sachs had brought—in words which have since become famous: "Pa, this requires action!"

National Affairs

By PETER EDSON
NEA Washington Correspondent

WASHINGTON, Dec. 1—The Senate's atomic bomb investigation got off to an awful start Tuesday, when a self-styled economic Jeremiah named Alexander Sachs took the witness stand and for two hours refused to let go. In that time he delivered a non-stop lecture on the history of civilization that was far deadlier than any atomic bomb ever concocted.

The committee room was small and crowded. The air was warm. The cigars smoked by Chairman Brien McMahon (Dem., Conn.) and Sen. Tom Connally (Dem., Tex.) were strong. Maybe it was the atmosphere and not the first atomic witness's testimony. But in the interests of accurate reporting, it must be recorded that towards the end of the proceedings, Senator Connally's lowest chin drooped to his vest and his eyes closed. Sen. Arthur Vandenberg (Rep., Mich.) propped his chin in the angle of his thumb and first two fingers and his eyes closed too. They were concentrating.

Anyway, when the quorum came for the senators to get back to the floor of the Capitol at high noon, Brother Sachs still had five years to go. He had got from his version of Genesis, "In the beginning there was a political concept and a moral concern," up to June, 1940, which marked the fall of Paris to the Germans and the appointment of another committee by President Roosevelt. Chairman McMahon tried several times to stop the lecture, but Alexander Jeremiah Sachs paid no attention and went blithely on, quoting from Exodus, St. John, Clemenceau and the Irish poet Yeats, and having a fine time. It was his day and he enjoyed it thoroughly, whether anyone else did or not. Maj. Gen. Leslie R. Groves sat around for an hour, twiddling his thumbs and waiting for his chance to testify, but he never got a word in and was told to come back the next day.

Probably Be Heard From Again.

Chairman McMahon at the end, getting in the next-to-the-last words, said Mr. Sachs might come back at some later time, to finish his statement, but he wasn't very specific as to when. You'll just have to guess at what happened between 1940 and 1945. What Brother Sachs had to do with the atomic bomb never did come out quite clearly, although the modest inference was that it was practically everything.

At one point Sachs said his role was to be a "resonator" to the President's ideas. At another point Sachs said Roosevelt said to him, "Pa Watson's going to be too busy to be historian, you've got to be it." At still a third point Sachs said he did not hesitate to be a glorified messenger boy. Maybe that's what resonator and historian mean—messenger boy.

Anyway, Sachs finally admitted coyly, without anyone asking him, that he was the man who carried the first memo on atomic energy from Albert Einstein to President Roosevelt. This was his fame and it rates him right alongside Paul Revere, the fellow whose name nobody can remember but who carried the message to Garcia, and the three other fellows who brought the good news from Ghent to Aix. Boy, page Albert Hubbard and two poets.

He Comes From Russia.

Sachs is quite a guy, no fooling. Big body, big bald head crowned by a fringe of gray hair that stuck straight up like Caesar's wreath. His eyes bulged behind thick-lensed, heavy horn-rimmed glasses. He spoke rapidly, his voice high and at times cracking. He was born in Russia 52 years ago, came to America in 1904, graduated from Columbia and Harvard and became vice president of Lehman Brothers, bankers. Probably in charge of the philosophical window. And don't ever say big investment houses do not have souls. The soul of Mr. Sachs is as big as history. For a time, he was economic adviser to the late Gen. "Iron Pants" Johnson, back in NRA days. This could explain a lot of things but probably doesn't.

Mr. Sachs did other things besides carry memoranda to Roosevelt. He wrote messages to Roosevelt on the state of the world. Then he took them to him and read them aloud. This was to impress the President with their contents, so that the material came to him "by ear and not by way of the mascara of the eye."

Under our social system, Mr. Sachs said to the senators, "You gentlemen are punch drunk from printer's ink." The senators all laughed at that. Printer's ink isn't the only thing you can get punch drunk on.

He Told F. D. R. Americans Were "God's Frozen People"

How Alexander Sachs Sold President on Developing Atomic Energy

By K. S. BARTLETT

An alert young man with most eager eyes and an intense curiosity about almost every subject in the world—

Talkative, with a passion for big words and long sentences, but able to be a good listener, too—

Gifted with a notable amount of personal magnetism—

That's how some New Englanders remember Dr. Alexander Sachs, New York economist, recently in the news as the man credited with selling the late President Roosevelt on atomic research more than six years ago.

Talked Law While Shaving

"I remember him as studying philosophy and we were in some of the same classes," said Prof. Raphael Demos, now an associate professor of philosophy at Harvard, "As I recall it he was talkative in class and had a tendency to use long sentences, as it is said he still does."

Prof. Demos and Sachs both roomed in Divinity Hall, one of the smaller and least pretentious of the Harvard dormitories back in the early days of World War I. Sachs was then enrolled in the Graduate School of Arts and Sciences and held a Francis Parkman fellowship.

"He was interested in law, too," recalls Demos, "and was a great admirer of the late Justice Brandeis. I can remember mornings we'd talk about law while we were shaving."

A Boston editorial writer who did much of his work in the evening in those days remembers that young Sachs used to drop in to see him from time to time.

"I can't remember what we talked about," he says, "but what I do recall even after all these years is the vivid and charming personality of the boy and his gift for talking interestingly about all kinds of things. I can't imagine him ever saying a stupid or trite thing."

Another local professional man with whom Sachs has corresponded for some years on a variety of subjects, although they never met, says his letters leave the impression of

ALEXANDER SACHS

Asked a President to "Please pay attention"

"a very bright and clever mind," with a "definitely journalistic tinge."

It may have been that last quality which helped him as a Washington correspondent phrased it the other day, "to draw back the curtain on nuclear fission for Mr. Roosevelt.

Here's the story as Sachs himself told it before the Senate "Blue Ribbon atomic energy committee recently. His friend, Prof. Albert Einstein, had studied a report made back in 1939 by the American physicist Dr. Leo Szilard, recounting his own experiments and those of Prof. Enrico Fermi, a fugitive from Fascist Italy. They were worried as Einstein was over the possibility of an enemy country developing atomic explosives.

Sachs knew the President, having met him frequently while in Washington with NRA. Einstein thought him the man to bring the whole matter to the Chief Executive's attention. So Sachs started for Washington armed with a letter from Einstein suggesting government development of atomic energy, the report and memorandum prepared by Szilard in something as close to every-day language as you can get in writing about atomic energy.

This was in September, 1939, and Mr. Roosevelt was almost buried in the avalanche of work which followed the German invasion of Poland. It took Sachs some time to get an interview, which turned out to be the first of several.

He read his three papers aloud—something he likes much better than merely handing them over to be read—and added an argument of his own. Then the President knifed through to the heart of the problem.

"Alex," he said, "what you're after is to see that the Nazis don't blow us up."

"This Requires Action"

Then, says Sachs, the President called his aid, Maj Gen Edwin M. Watson, and said:

"Watson, this requires action."

Friends say that Sachs in some of the interviews eased the President into the discussion "with a few learned jokes." Geoffrey T. Hellman, writing in The New Yorker, says Sachs disclaims this.

"I'd just tell him I'd paid for the trip to Washington and couldn't deduct it from my income tax and would he please pay attention," Hellman quotes Sachs as saying, "I once made a joke about Americans being God's Frozen People during the wartime freeze on everything—to which incidentally I was in some particulars opposed."

According to the testimony before the Senate committee President Roosevelt told Watson to bring Dr. Sachs and Dr. Lyman J. Briggs, then director of the Bureau of Standards, together and have them set up a working committee. This was done. The Briggs Committee eventually became a sub-committee of the National Defense Research Committee, headed by Dr. Vannevar Bush, which was created during the Summer of 1940 and thereafter Dr. Sachs as he put it recently, "provided for his own disappearance" from the picture.

He had been, so Gen "Wild Bill" Donovan wrote him recently, "the deft intermediary between committee room, laboratory and planning board" and "the nation is indebted to you for the catalytic function which you performed."

Russian-born Sachs is 52 now, with fluffy, iron gray hair, well gone on top. Although he came to this country when he was 11 years old some still notice a faint trace of accent at times. He was a brilliant youngster and was only 19 when Columbia gave him a B. S. degree.

There followed a period as a clerk in the New York office of the old firm of Lee, Higginson & Co.

Had Parkman Fellowship

Next Harvard, in 1915, with the Parkman Fellowship. In 1916 he enrolled for jurisprudence and was awarded the Henry Bromfield Rogers Memorial Fellowship for the study of ethics in relation to jurisprudence or sociology.

He went back to Wall Street shortly and became an economic adviser and consultant. His work branched into many fields as his writings show. Recent ones include an article on taxation, on strategic materials, and on the logistics of petroleum pipelines as compared with tanker construction. He was for many years connected with the Lehman Corporation, an investment trust, managed by Lehman brothers, becoming a vice president in 1936, and resigning in 1942 to become an independent economic consultant.

He wouldn't, it is said, please the exponents of the "clean desk" theory.

"Sachs," says an interviewer, "likes to carry research around with him and is the possessor of 40 second-hand brief cases, a birthday gift from some jocular Lehman Corporation officials. His pockets are stuffed with memoranda which he deposits in a pile on the floor when he is looking for something.

"And both in writing and in conversation he uses such phrases as 'if only we could overcome the sclerotic-ism of the Right and the infantilism of the Left.'"

Which roughly is the economist's way of mentioning the troubles arising out of the lack of sensibility or stubbornness of the Right and the childishness of the Left.

That presumably is the sort of thing some of his one-time dormitory mates at Harvard remember. And one suspects too that he gets as much kick out of trying out such—or much more—exotic phrases on the layman as a Southwestern University football coach does out of his latest razzle-dazzle.

For Better Living!

If you plan to build, you'll want the extra comfort and economy of Timken steam, hot water, or warm air oil heating. Thousands of owners say you can't get a better buy at any price. Order now! Our new complete units with postwar improvements will be ready for installation by the time most new homes are ready for heating systems.

In your present home, if your heating plant is in good condition, you can install a new improved Timken Silent Automatic Conversion Oil Burner as quickly as deliveries permit. You can forget all heating worries. You'll save up to one gallon of oil in every four used by an ordinary burner. You'll have the quietest, most dependable oil burner modern oil heating science can build.

PERMANENSEAL COMBINATION Storm and Copper Screen WINDOWS

WINTER Comfort

Plus a fuel saving as high as 30%! Glass or screen in or out—in a jiffy. Easily washed or ventilated—all done from the inside.

In SUMMER

Keep cool with KOOL-SHADE. It screens out the sun rays—lets in the light and air—eliminates sun fading of rugs, drapes, etc.

REVEALS ROOSEVELT SCHEME FOR WARNING THE WORLD

How F.D. Planned to Use Atom Bomb

DR. ALEXANDER SACHS

How a secret memorandum influenced the vital A-bomb decision . . . how a story about Napoleon moved Roosevelt to commit the United States to use of the bomb . . . why the President listened to Alexander Sachs . . . and: Did Roosevelt, in his last months, change his mind about how to deal with Russia?

The Boston Globe (Boston, Massachusetts) • 27 Feb 1950, Mon • Page 1

(These questions are all answered in a startling copyrighted article which will appear in Look Magazine, out tomorrow, and printed in advance here, by special permission of the publishers.)

By NAT S. FINNEY

What did President Roosevelt intend to do with the atomic bomb?

It is a strange fact that the biographies and memoirs of Roosevelt's official associates supply no answer to this question.

Dr. Alexander Sachs, recognized in the famous Smyth report as the man who persuaded Roosevelt to launch the atomic-energy project, has now come forward with an answer.

The President, he says, planned to demonstrate the bomb before international representatives of governments, science and religion, before he ordered it dropped on America's wartime enemies.

Dr. Sachs, a New York economist and student of the history of science, bases his assertions about what was in F. D. R.'s mind when he aied on conversations he had with Roosevelt as late as December, 1944.

A memorandum advocating a new political strategy to bring about the surrender of Japan without the long, to-the-last-man struggle foreseen by the War Department General Staff was read by him to Presicent Roosevelt immediately before the 1944 elections, Dr. Sachs says. F. D. R. expressed agreement with the ideas contained in the memorandum, and told Maj Gen Edwin (Pa) Watson, his aid, about his views. This memorandum contained an idea Dr. Sachs submitted in a letter of May 8, 1944, which the President acknowledged by a letter to Dr. Sachs. In this May, 1944, letter it was urged that "victory over Germany would accelerate the defeat of Japan" far earlier than the military believed.

A Plan to End the War with Japan

"Final Phase European War and Emerging Opportunity for Liquidating Far Eastern War," was the title of this memorandum. It refers to the atomic bomb only in the code words "exponential weapon." But the meat of the policy it put forward was that with use of the atomic bomb in a series of dramatic warnings, Japan's Ruling House, along with groups that could point to a record of resistance to the Japanese militarists, could regain control of Japan. And that, in view of the utter hopelessness of the outlook of Japan from the Spring of 1945 on (with Germany defeated) the Japanese Emperor would accept surrender terms.

These terms, Dr. Sachs says, aimed at a "constructive use of the institution of the Emperor, with safeguards."

Dr. Sachs says the broad plan, in which use of the bomb was an integral part, had been set in motion before Roosevelt death at Warm Springs, Ga., in April, 1945. James V. Forrestal, then Secretary of the Navy, had recalled Capt (now Admiral) Ellis M. Zacharias from the West Coast to prepare the series of broadcasts in Japanese that played their part in Japan's ultimate surrender.

[HN00IQ][GDrive]

Sachs Pleaded With Roosevelt to "Tell Someone" of His Decision to Use A-Bomb

Continued from the First Page

(Editor's Note—Henry L. Stimson, Secretary of War in 1945, has described the War Department General Staff's estimate of the Far Eastern war situation in July, 1945, in a way that pictures the alternative to Dr. Sachs' suggestions for ending hostilities: "The strategic plans of our armed forces for the defeat of Japan, as they stood in July, had been prepared without reliance upon the atomic bomb. . . . We were planning an intensified sea and air blockade, and greatly intensified strategic air bombing, through the Summer and early Fall, to be followed on Nov. 1 by an invasion of the southern island of Kyushu. This would be followed in turn by an invasion of the main island of Honshu in the Spring of 1946. The total United States military and naval force involved in this grand design was of the order of 5,000,000 men; if all those indirectly concerned are included, it was larger still. We estimated that if we should be forced to carry this plan to its conclusion, the major fighting would not end until the latter part of 1946, at the earliest. I was informed that such operations might be expected to cost over a million casualties to American forces alone.")

Forrestal Returned from Pacific In State of Emotional Shock

The relationship between Dr. Sachs and President Roosevelt was known to close mutual friends. But the extent of Dr. Sachs' activities as a personal, nonofficial adviser on atomic energy and grand strategy is little-documented, except in Dr. Sachs' own files.

The President's executive officer on some matters of atomic energy was General Watson. Forrestal, who Dr. Sachs says returned from the Pacific in a state of emotional shock that impelled him to reach for any honorable way to end the war, was intermediary with Zacharias. Roosevelt, Watson and Forrestal are dead.

Dr. Sachs' lips were sealed by a pledge of secrecy to Roosevelt himself. He did not feel himself released until the Smyth report disclosed how he labored to persuade F.D.R. to undertake the atomic energy project, and even then he felt doubt about describing his association with the project during late phases of the war. He has discussed this association with acquaintances in conversations and letters, but the public has not heard the story.

I have examined Dr. Sachs' records of his conversations, and copies of the memoranda he used as the bases of his discussions with President Roosevelt. Here is Dr. Sachs' version of the last chapter of President Roosevelt's life:

Its roots go 12 years deep in time, back to 1933 when Dr. Sachs was still Governor of New York and campaigning against Herbert Hoover for the Presidency. Dr. Sachs, then, and up to the war, with Lehman Corp., and since an independent consultant and director of Lehman Corp., had won himself a reputation in England and the United States as an economist of unusually deep grasp of monetary matters.

Through mutual friends, Roosevelt asked Sachs' advice on a projected campaign speech on the gold standard. Sachs tells how he responded with a suggestion that, instead of making a derivative speech, the subject be assigned to the late Senator Carter Glass, who was a master in his own right.

F.D.R. heeded Dr. Sachs' counsel, and appreciated the refreshing candor with which it had been given. Thus began an unusual association of two men as American history records.

Its culmination came in February of 1945, just before the failing President left Washington for Warm Springs. In the course of a long relaxed conversation at the White House President Roosevelt accepted the view of world events Dr. Sachs says he first put forward in April of 1941—the view that American policy could not be based upon expectation of a friendly and cooperative Soviet Union.

The President undertook to reconsider the philosophy underlying his administration's expectation of a postwar era of one-worldism and to take under serious advisement the revision of the policy he therefore had followed.

He agreed, says Dr. Sachs, with the contention that the ordinary state and military agencies of the Federal Government were so fixed in the patterns of the old policy they could not hope to develop a new one. They suffered, Dr. Sachs explains in his own phrases, from hardening of the categories, blinkered thinking, encrusted ideas.

Roosevelt planned to name Lewis Douglas, Dr. Sachs and one other man, not designated when F. D. R. died, to a special Presidential commission that would make a fresh review of the facts and present fresh conclusions forcibly as to command the change F. D. R. might seek.

Plans for using the bomb had an earlier culmination. This occurred after the 1944 elections, during the first week of December to Dr. Sachs' recollection.

Roosevelt and Sachs met at the White House where Sachs says he read what is here called his lost memorandum. At the conclusion of the two men's long conversation, the President nodded his agreement to Dr. Sachs' proposals for the use of the atomic bomb.

"For God's sake tell someone," Sachs pleaded.

The President agreed to "tell Pa" (Gen Watson). Dr. Sachs is satisfied that Gen Watson was told. His plea to President Roosevelt that someone be told was prompted by his own observation that F. D. R.'s powers were overstrained, and his anxiety that he, who had been insistent upon holding no official position whatever, might not be sole possessor of such a secret.

The President, in Dr. Sachs' poignant phrase (he thinks it comes from Shakespeare but cannot find the line) was becoming "disorderly minded."

Lengthening pauses spaced F. D. R.'s conversations with Dr. Sachs, pauses during which the President was there, yet in a sense not there.

The line and conference of F. D. R.'s thought was not broken by these pauses, which Dr. Sachs respected in silence, but the continuity of the President's on-pressing drive was momentarily suspended as if he listened inwardly to another, private harmony.

Our Enemies Would Be Warned

Here, as recaptured later by Dr. Sachs in a letter to Secretary of War Robert P. Patterson, is the proposal for the atomic bomb's use with which F. D. R. expressed agreement in December, 1944.

"Following a successful test, there should be arranged (a) rehearsal demonstration before a body including internationally recognized scientists from all Allied countries and, in addition, neutral countries, supplemented by representatives of the major (religious) faiths; (b) that a report on the nature and the portent of the atomic weapon be prepared by the scientists and other representative figures; (c) that, thereafter, a warning be issued by the United States and its allies in the Project to our major enemies in the war, Germany and Japan, that atomic bombing would be applied to a selected area within a designated time limit for the evacuation of human and animal life, and, finally (d) in the wake of such realization of the efficacy of atomic bombing, an ultimatum demand for immediate surrender by the enemies be issued, in the certainty that failure to comply would subject their countries and peoples to atomic annihilation."

(Dr. Sachs' recommendation that representatives of the major religious faiths attend the atomic bomb demonstration called for something more than Catholics, Protestants. . . . He wanted representatives of Judaism, Mohammedanism and Buddhism.)

Facts Have Been Twisted

This was the understanding in early December of 1944, and so far as Dr. Sachs can recollect or was informed, it remained the understanding until President Roosevelt's death on April 12, 1945.

Yet a simple restatement of the plan as put down by Dr. Sachs in July, 1946, from his memory of the memorandum, can lead to profound misunderstanding of what was in the mind of Dr. Sachs and President Roosevelt when they last discussed their shared secret of the vast atomic explosion about to be unleashed.

Indeed, incomplete information about the plan on which the minds of Dr. Sachs and Franklin Roosevelt then met has already been tortured and twisted to make it appear that had Roosevelt lived Hiroshima and Nagasaki would never have occurred.

(Editor's Note—This is not, as might appear to some, a denial that F. D. R. had planned to demonstrate the bomb before using it as a military weapon. Dr. Sachs is simply making it clear that neither he nor anyone else can be sure of what F. D. R. would have done had he lived to face the situation existing in August, 1945. The Roosevelt plans called for more atomic bombs than actually existed in August, 1945. Obviously, Dr. Sachs could not know how this and other technical facts might have caused F. D. R. to change his plans.)

It has been whispered that President Truman knowingly brushed this plan aside in favor of the actual use of the bomb decided upon by an interim committee headed by Secretary of State James F. Byrnes and Secretary of War Henry Stimson.

This committee, Secretary Stimson records, submitted its conclusions to a panel of distinguished scientific advisers who, partly because they could not, in the light of the facts, suggest an alternative, raised no objection to the way in which the bomb was used.

Dr. Sachs emphatically disagrees with those who argue that the American-British-Canadian team of nations that made the bomb is morally guilty for the use made of it. While he continues to believe that his broad sense of his proposal for a demonstration under international, inter-religious auspices of the weapon's powers could have been made when the bomb was tested at Alamogordo, N. M., he is convinced that the essential features of President Roosevelt's plans for using the bomb were carried out.

Dr. Sachs decries the kind of "apocalyptic thinking" that makes the precise use of the atomic bomb the central overshadowing item in the unfolding of the President's much-more-comprehensive plan to bring about the surrender of Japan through negotiations with Hirohito after our facilitating a political coup d'etat.

Warning to Japan

He points out that there was a warning to Japan—numerous warnings culminating in the ominous Potsdam Declaration. He continues in the belief that had these warnings been sharply dramatized by such a disclosure of the bomb's awful powers as he conceived, Hirohito might well have been able to regain control earlier.

Yet, he emphasizes, it was the bomb's terrific impact that sealed victory in the psychological war. President Roosevelt had set in motion by having Capt Zacharias recalled to Washington to speak to Japan in Japanese that forehandedly fully included ceremonial and archaic language to appeal to the court and high naval and other officials.

Dr. Sachs has only praise for the responsible men who made the fateful, final decisions in carrying through broad plans that were never seriously questioned by Roosevelt's successors, despite the great unpopularity of all suggestions that a deal should be made with the Japanese Emperor.

History Teaches F. D. R.

He has a sharp word for persons who now give currency to an American "guilt complex" at the use of the bomb. He compares this "self-denigration" to the sobs-thinking about Germany which followed World War I, and he warns that the upshot could be similar.

His story of the conversation with President Roosevelt, during which a decision was reached on use of the bomb as an integral part of ending the slaughter in the Pacific, suggests that Roosevelt may have been weighing in his mind all the political and moral implications of the use of the bomb.

(It must be remembered that in December, 1944, there was no certainty the weapon could be made or would be ready in time to provide a sign or shocking accent to hasten the end of the mounting horror by other weapons of scientific killing.)

Dr. Sachs says his way of dealing with President Roosevelt was to prepare a careful memorandum and read it aloud, pausing to discuss any fact or concept that raised a question in F. D. R.'s mind. Sachs would then attempt to support a crucial point by a story drawn from history—Roosevelt was an avid, ranging reader of history with relish for a telling passage, particularly when it was new to him.

The discussion on this December day revolved about the subtle point of a statesman's responsibilities to history, and the rightness or wrongness of visiting the world with a new agent of destruction. Dr. Sachs was ready with a story.

You Can't Bury a Discovery

Toward the end of the 16th century, John Napier, the Scotsman who invented the logarithmic tables, became greatly interested in engines of war because of his Protestant zeal that Britain should never fall to such a threat as the Spanish Armada.

Napier's biographer and descendant, Dr. Sachs told the President, learned that the Scotch mathematician had not only devised such weapons as sets of burning mirrors and primitive tanks, but had come upon an invention which succeeded in annihilating all animal life in an area of a square mile.

His biographer, Sachs told President Roosevelt, recounted that Napier was "so disquieted that he buried the machine," feeling that "mankind had many engines with which to destroy each other and that . . . he could never willingly increase them."

With this story as his key, Dr. Sachs says he convinced President Roosevelt that it was neither possible nor desirable to suppress such a discovery as was being brought to birth within the Manhattan District.

He saw the bomb as the climax of human technological achievement, linked to the most fundamental forces of nature. Its use would be a readily readable sign to the whole of humanity, and would, therefore, foreshorten the war and save millions of lives of our own and the Allies, and our enemies as well. But that the weapon must, at the very least, be demonstrated so that the complexities of its impact upon human development would be felt.

This, in its strange and somewhat indirect way, was the crux of the President's decision—a decision with an elaborate background that can be understood only by some grasp of the relationship between F. D. R. and his most unusual confidential adviser.

Sachs Spoke Out

The beginning of this relationship has been described. At their first meeting, President Roosevelt found that Alexander Sachs was an enormously well-informed man who preferred complete anonymity and had no desire whatever about differing with the President when he believed him to be in error.

Few who knew Roosevelt well can be surprised that he formed an attachment to Dr. Sachs. The attachment grew through the years. It grew for reasons that are clearly on the record.

In his own and related fields—modern economics—Dr. Sachs has a startling record of having been among the few pack of more orthodox thinkers was wrong. He helped frame the National Recovery Administration would be a failure and be held unconstitutional, and very frankly advised F. D. R. of what he anticipated. Yet he backstopped the late Hugh Johnson through the NRA days. There are numerous other instances of the sort.

One central belief held steadily by Dr. Sachs in the years when World War II was gathering was the key to his peculiar helpfulness to Roosevelt. Sachs demonstrated historically that the Great Depression was something more profound than a collapse in the economic sphere. It was a collapse of the Great Culture of Western Europe. During the 1932 campaign, Dr. Sachs asked F. D. R. whom he considered his principal opponent. "Why, Herbert Hoover, of course," the New Deal candidate replied. "You are wrong, Mr. Roosevelt." Sachs says he told his friend. "Your enemy is Adolf Hitler."

He Saw War Coming

Long before other advisers to F. D. R. warned him that the great threat was aggression by the dictators, Dr. Sachs was correctly interpreting events in Europe and Asia.

Partly because of his deep feeling of alarm about the oncoming war, Dr. Sachs kept a sharp eye on unorthodox events in the scientific world. As the 1930's drew toward their end, a providential combination of circumstances made Dr. Sachs perhaps the only man who could have advised President Roosevelt about atomic energy.

His long record of giving the President sound advice in economic matters caused F. D. R. to rely upon him. His steadfast refusal to accept any public favor or assignment convinced Roosevelt he had discovered a counselor who genuinely desired anonymity.

Dr. Sachs' lifelong interest in fundamental science (he is reputedly a first-rate mathematician) caused him to follow and understand the emergent possibility of unlocking the huge energies inside the atom. He attended a series of lectures in England in 1936-37 at which Lord Rutherford and F. W. Aston clearly indicated atomic energy. At the beginning of 1939, he secured one of the few careful translations made of the historic Hahn-Strassmann report on atomic fission.

During the latter phases of the Nazi purge of non-Aryan members of the great German scientific community, Dr. Sachs became interested in helping those who needed to be rescued. He got acquainted with some of these emigre scientists in the course of his professional trips in England. Others came to the United States and Canada. Through them, Dr. Sachs got the most expert, personal advice.

Thus, in the Summer of 1939, when the Navy Department flatly turned down proposals for an atomic project, Dr. Sachs was being told by such men as Drs. Leo Szilard and Eugene Wigner that the possibility of atomic weapons could not be neglected.

1939: Year of Decision

Dr. Sachs says he undertook to familiarize President Roosevelt both on the scientific possibilities of atomic energy, and the political possibilities if Germany became able to terrorize the democratic world with an atomic devastator. It is hard now to recall what things were like in early 1939. Austria had been swallowed by Hitler in 1938. Czecho-Slovakia, deserted by shock-sick England and France, had been taken over without a shot. The United States had no means for offensive war.

Dr. Sachs says he became F. D. R.'s personal Jeremiah on the subject of technological warfare because of real fear that Germany might succeed in terrorizing the whole world.

During the late Summer of 1939, Dr. Sachs says he broached the subject with President Roosevelt about starting an atomic project. The President was so preoccupied with problems of the neutrality act that he could not then give the matter attention.

The story of how Dr. Sachs enlisted Dr. Einstein to contribute a supporting letter to the dossier of material he used to convince the President is told in the Smyth report, and Dr. Sachs' testimony before the Congressional atomic energy committee fills in a good deal of detail. But Dr. Sachs has never publicly told the story of the crucial meeting at which President Roosevelt decided to commit himself to making an atomic weapon.

Roosevelt Not Convinced

On Oct. 11, 1939, Dr. Sachs read a long letter-memorandum of his own to President Roosevelt along with the letter signed by Dr. Einstein and a joint memorandum signed by Dr. Szilard and himself. The President was impressed and willing to help, but not convinced he should embark on such a costly course of action under government auspices.

(Dr. Sachs later advised him that producing an atomic weapon might well cost two billion dollars on the basis of the telescoped cost of electrical power in the years before World War I.)

Dr. Sachs says he asked President Roosevelt if he could see him the next day. The President invited him to come to breakfast.

Dr. Sachs tells how he spent most of that night either at his room at a Washington hotel, or in nearby Jackson Park, trying to think of something he might say that would bring the President to order a study of the feasibility of atomic weapons.

He recalls returning to his hotel room at dawn, and of dozing in a chair while waiting the operator's wake-up call. He did not go to bed for fear he would lose the thread of what he wished to tell the President.

He came back to the White House, he says, to find Roosevelt seated alone at his breakfast table while a servant attended him. As he sat down, the President said:

"What bright idea have you got now? How much time would you like?"

Dr. Sachs says he replied that he would not take long. "All I want to do is tell you a story." This is Dr. Sachs' recollection of the story:

Lord Acton and the Atom Bomb

He told the President that many years before, while he was in his final year at Columbia University, he had become acquainted with a philosopher and theologian, Prof. Dickinson Sergeant Miller. Later, in 1915, through this friendship, he met and talked to a visiting British divine, Rev. John Neville Figgis. Fr. Figgis, he explained to President Roosevelt, had written a book on political theory, entitled "From Gerson to Grotius." This interest in European politics caused Fr. Figgis to be chosen as literary executor and editor of the lectures and writings of Lord Acton, a famous English political historian with whose work President Roosevelt was acquainted.

Fr. Figgis, Dr. Sachs told President Roosevelt, discovered that Lord Acton had been asked an unusual question about English history. Could Lord Acton mention an outstanding instance of England being saved from national peril, not by its own efforts, but by the failure of an enemy to seize advantage of an opportunity to destroy England? Dr. Sachs explained that, according to Fr. Figgis, Lord Acton asked a day to consider the question.

Napoleon Blunders

The next day, Dr. Sachs told President Roosevelt, Lord Acton was ready with his answer. There was an outstanding example of how England had been saved by an enemy's mistake.

During the Napoleonic Wars, after Bonaparte had tried to land his armies on England's shores and failed because of the English Channel's trick tides and currents, a young American inventor came to the French Emperor with an idea.

The inventor was Robert Fulton, and his idea was that Napoleon build a fleet of steamships that could overpower the channel's currents. Then Napoleon would be able to land his armies, and a helpless England would be at his mercy.

Dr. Sachs repeated Lord Acton's story of how Napoleon scoffed at Fulton's idea. And he told President Roosevelt how Lord Acton held that if the French Emperor, then at the zenith of his power, had only had the humility and the imagination to entertain a new idea the 19th century history of England might have been far different.

Dr. Sachs says President Roosevelt sat silent when he had finished his story. "That seemed like a very long silence to me," he recalls. "I suppose it was two or three minutes, but it seemed like half an hour."

The servant, Dr. Sachs remembers, was clearing away the dishes and, without saying anything, President Roosevelt scribbled something on a piece of note paper and handed it to the servant. A moment later the servant returned with a tall package. When he unwrapped it, Dr. Sachs saw it was a magnum of Napoleon brandy. The servant drew the cork, and not until then did Mr. Roosevelt speak. He ordered the servant to pour.

A Toast to the Future

When each man, President Roosevelt and Dr. Sachs, held a penny of the old brandy, the President clicked his glass with Dr. Sachs and drank. Then, with a friendly gesture, he told Dr. Sachs he would take action on atomic energy. General Watson was directed to follow through.

Bank Cancels Mortgage!

SBLI Our new Home Protector Plan makes sure your family doesn't lose your home when they lose you. It pays off the mortgage; costs but pennies a day to carry because it uses the lowest-cost kind of Savings Bank Life Insurance. A VOLUNTARY, NON-PROFIT HOSPITALIZATION PLAN
IS ALWAYS THE HEALTHIEST WAY
A Financial Report
to the People of Massachusetts

FOR THE YEAR 1949

Blue Cross received from members	$22,306,360.53
Blue Cross paid hospitals for care of members	16,094,264.70
Addition to mandatory reserves for future protection of Blue Cross members	4,329,527.84
Other addition to Reserve for future protection of Blue Cross members after deducting 5.8%* for operating expenses	904,662.53

*The extremely low Blue Cross operating expense of only 5.8% ensures every Blue Cross member of the greatest hospitalization service at the lowest possible cost.

Blue Cross is strictly a non-profit service. It is the only non-profit hospitalization plan providing service benefits available to the people of Massachusetts.

Massachusetts citizens believe in self-protection

Since 1937, when Blue Cross first offered its benefits, more than half the population of Massachusetts has wanted and joined Blue Cross. For services to these members, $88,013,832.02 has been paid by Blue Cross to Massachusetts hospitals, supporting the plan. This has been for all types of services to all types of members... men, women, and children . . . services that many would be unable to pay for without Blue Cross.

This is a healthy situation. Men and women believe in protecting themselves...the voluntary way...the honorable way. They ask no charity. They want no charity. And they have found in Blue Cross the means of paying for their health protection at the lowest possible cost.

Blue Cross is still growing stronger and stronger. It increased its benefits last June. It intends to increase its benefits further in March. Always, Blue Cross will continue to be the "best buy".

If you are not a BLUE CROSS Member, find out about all its advantages. Send coupon today.

Behind The Headline

The Fate Of Man In Balance

By ERNEST CUNEO

New York — There is a legend attached to the inception of the atomic bomb and, unlike most legends, there is substantial fact behind it. The legend:

When Alexander Sachs, New York financier and industrialist, brought Einstein's document to President Roosevelt the President was unconvinced. The mind of Alexander Sachs, sleepless throughout the night, sought for a clinching argument and found it. He appeared early at the White House the next morning. He told the President that after Napoleon had conquered Europe he raved and ranted because he could not attack England. The British fleet in the channel barred his way, and Napoleon raged that he could not defeat an enemy whose allies were the winds and the tides.

Defeated by What?

After weeks of this one of Napoleon's ministers timidly ventured the suggestion that Napoleon see a young man in Paris who claimed he could conquer the ocean floods. Napoleon finally consented to see him. He asked him to what service he belonged. The young man answered that he belonged to none, he was not a military man. Napoleon became brusque. Commissioned in no army? Ranked in no navy? The young man answered in the negative. "Throw him out," screamed the Emperor, "it is an imposition on his Imperial Majesty to take up time with these people."

The young man was ushered out. Alexander Sachs then made his point to the President. The young man whom Napoleon refused to hear was Robert Fulton. Under his arm he had the plans of the first steamboat, with which Napoleon could have circumvented the British fleet and invaded England.

Sachs made a further point. He told the President that while the verdict of history was that Napoleon had been defeated by the snows of Russia, he lost because of his own lack of imagination. The President, a man of imagination, saw the point, and at once acquiesced to the Manhattan project, named in honor of Sachs, according to the legend.

And Today's Thinkers

As a slight fillip to the same legend the President is then said to have opened a bottle of cognac, given to his grandfather by Napoleon.

It took daring new thinking evident merit 1966 might well be the year to dust off the Baruch plan and try it again. For one thing, Moscow seems to have now discovered, as the United States perceived early, that the weapon a man carries may be the cause of his death, for if people become afraid of his using it they will shoot first.

The idea of a world only 10 years away in which any one of 15 nations could destroy tens of millions of people and half a continent in 24 hours is a nightmare from which all civilized men, including the Soviet scientists, recoil.

At the time the Baruch proposals were made President Harry Truman expressed the hope and belief that nuclear weapons would blow the world together, not apart. No nation has the right to give up trying. Indeed, the warning of Prime Minister Wilson is more than 2,500 years old, because over and above all of its augurs the Delphic oracle proclaimed, "Remember, O Greek, that necessity is above the gods themselves."

That same daring human imagination which promulgated nuclear weapons must now be employed to save mankind from them. The Baruch proposal, reintroduced, might well start off a chain reaction of imaginative nuclear control.

Voice Of The People

Genovese Again

(A forum for readers' comment on matters of public interest and on this newspaper's editorial opinions. Like Voltaire, we may disagree with what they say but will defend to the death their right to say it. Letters will not be published without signature and full address.)

Editor, The Call:

I have seen everything now. This can only happen in the United States. A man like Genovese wants a year's leave of absence with pay when he becomes eligible in July, which is 3 years at Rutgers.

In the whole country would any other industry give you a year's pay to go and write a book, which no doubt will show this country as being no good. My son and other teachers in this city have been drafted, even with the shortage of teachers, and sent to the Far East. They are not going to get any year's leave of absence with pay, only the $100 a month the Army pays. No wonder our taxes are high! Mr. Governor, now make a speech and say something about the Bill of Rights. While I am on the subject of Mr. Genovese I would like to know where the ones who took his part and find fault with this country's being in South Vietnam were when Russia went into Hungary to crush the Hungarian revolt.

Editor, The Call:

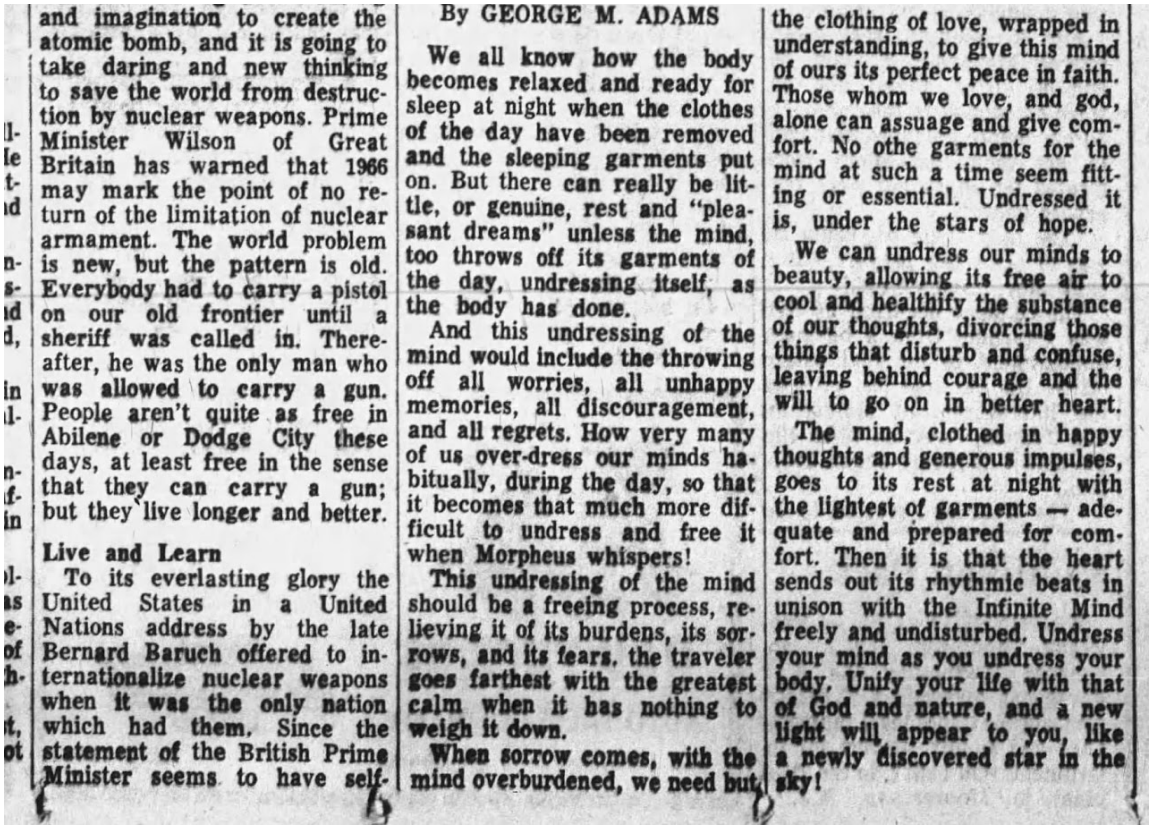
The Tenants Council of River View Towers would like to take this opportunity to thank you for the splendid coverage you gave to our organization during this year. We are grateful to you and your staff.

MARIAN DALTON
105 Presidential Boulevard
Paterson, Dec. 15, 1965.

Today's Talk

Undress Your Mind!



and imagination to create the atomic bomb, and it is going to take daring and new thinking to save the world from destruction by nuclear weapons. Prime Minister Wilson of Great Britain has warned that 1966 may mark the point of no return of the limitation of nuclear armament. The world problem is new, but the pattern is old. Everybody had to carry a pistol on our old frontier until a sheriff was called in. Thereafter, he was the only man who was allowed to carry a gun. People aren't quite as free in Abilene or Dodge City these days, at least free in the sense that they can carry a gun; but they live longer and better.

Live and Learn

To its everlasting glory the United States in a United Nations address by the late Bernard Baruch offered to internationalize nuclear weapons when it was the only nation which had them. Since the statement of the British Prime Minister seems to have self-

By GEORGE M. ADAMS

We all know how the body becomes relaxed and ready for sleep at night when the clothes of the day have been removed and the sleeping garments put on. But there can really be little, or genuine, rest and "pleasant dreams" unless the mind, too throws off its garments of the day, undressing itself, as the body has done.

And this undressing of the mind would include the throwing off all worries, all unhappy memories, all discouragement, and all regrets. How very many of us over-dress our minds habitually, during the day, so that it becomes that much more difficult to undress and free it when Morpheus whispers!

This undressing of the mind should be a freeing process, relieving it of its burdens, its sorrows, and its fears. the traveler goes farthest with the greatest calm when it has nothing to weigh it down.

When sorrow comes, with the mind overburdened, we need but the clothing of love, wrapped in understanding, to give this mind of ours its perfect peace in faith. Those whom we love, and god, alone can assuage and give comfort. No othe garments for the mind at such a time seem fitting or essential. Undressed it is, under the stars of hope.

We can undress our minds to beauty, allowing its free air to cool and healthify the substance of our thoughts, divorcing those things that disturb and confuse, leaving behind courage and the will to go on in better heart.

The mind, clothed in happy thoughts and generous impulses, goes to its rest at night with the lightest of garments — adequate and prepared for comfort. Then it is that the heart sends out its rhythmic beats in unison with the Infinite Mind freely and undisturbed. Undress your mind as you undress your body. Unify your life with that of God and nature, and a new light will appear to you, like a newly discovered star in the sky!

1968 - Involvement with LBJ / Nixon Presidential election

See [HX000C][GDrive]

On the thousands of hours of White House tapes Richard Nixon secretly recorded, you can hear him order exactly one burglary. It wasn't Watergate, but it reveals the real root of the cover-up that toppled a President.

On June 17, 1971, (one year to the date before the Watergate arrests, by impure coincidence) Nixon ordered his inner circle to break into the Brookings Institution. "Blow the safe and get it," the president said. "It" was a file of secret government documents on the 1968 bombing halt.

"What good will it do you, the bombing halt file?" asked National Security Adviser Henry Kissinger seconds after the president ordered his top aides to commit a felony.

"To blackmail him," Nixon replied. President Lyndon Johnson had halted the bombing of North Vietnam less than a week before Election Day. Nixon claimed LBJ did it for political reasons, to throw the election to his vice president, Hubert Humphrey.

Kissinger knew better, since he had inside information about the talks. Having worked on an abortive bombing halt deal for Johnson in 1967, Kissinger used his connections with LBJ's negotiators then to gain access to the Paris talks in 1968 -- access he used as a secret informant to the Nixon campaign.

"You remember, I used to give you information about it at the time," Kissinger reminded the president. "To the best of my knowledge, there was never any conversation in which they said we'll hold it until the end of October. I wasn't in on the discussions here. I just saw the instructions to [Ambassador Averell] Harriman," the chief U.S. negotiator in Paris. (Kissinger's words on tape contradict his later claim that he didn't even have access to classified information at the time.)

Nixon had his own reasons to realize that the bombing halt file didn't contain blackmail material on Johnson. He knew from classified briefings during the campaign that Johnson had remained unwavering in demanding three concessions: If Hanoi wanted a bombing halt, it had to (1) respect the DMZ dividing Vietnam, (2) accept South Vietnamese participation in the Paris peace talks, and (3) stop shelling civilians in Southern cities. Throughout the negotiations, LBJ didn't budge from these three demands. Hanoi remained equally adamant, insisting on an "unconditional" bombing halt -- until October 1968. Then Hanoi suddenly reversed course and accepted all three. Johnson didn't decide the timing of the bombing halt; Hanoi did.

If the bombing halt file didn't contain dirt on Johnson, what made Nixon want it desperately enough to risk impeachment and prison? Over the decades, evidence has slowly accumulated that Nixon had a far more compelling motive: the fear that the bombing halt file contained dirt on him.

Throughout the 1968 campaign, the Republican nominee promised not to interfere with the Paris talks. "We all hope in this room that there's a chance that current negotiations may bring an honorable end to that war," he told the Republican convention in Miami, "and we will say nothing during this campaign that might destroy that chance." Publicly, Nixon claimed to put the quest for peace above his own quest for votes, although it was clear that any negotiating breakthrough by Johnson before Election Day would help Vice President Humphrey's campaign.

One week before Election Day, Johnson got a tip that Nixon was trying to sabotage the negotiations. It came from a highly credible source, the legendary Alexander Sachs.

Sachs entered world history when, clutching a report from Albert Einstein, he warned Franklin Roosevelt in 1939 that Nazi Germany could corner the world uranium market and build an atomic bomb, a warning that led to the Manhattan Project. Sachs was also credited with predicting the Great Depression and the rise of Hitler, so he was not someone whose warnings could be safely ignored.

Sachs, chief economist for Lehman Corporation, informed Johnson that he had learned from Wall Street colleagues "closely involved with Nixon" that the Republican nominee "was trying to frustrate the president, by inciting Saigon to step up its demands, and by letting Hanoi know that when he took office 'he could accept anything and blame it on his predecessor.'"

By that point, North Vietnam had already accepted Johnson's terms. So had South Vietnam, privately, in meetings with the U.S. ambassador.

But America's allies in Saigon saw risk and opportunity in the upcoming U.S. presidential election. The risk was the election of Hubert Humphrey, a dove who had urged LBJ not to Americanize the war in the first place and whose supporters hoped he'd withdraw from Vietnam quickly if elected. The opportunity was to elect the premiere anti-Communist politician of the Cold War, Richard Nixon. All Saigon had to do to tip the election to their preferred candidate was refuse to take part in the Paris talks. No talks, no peace -- there could be no settlement of the war if one side of it refused to even negotiate. The hopes for peace stirred by the bombing halt would evaporate.

Once LBJ received the warning from Sachs, he took a closer look at diplomatic intelligence collected by the National Security Agency (which intercepted cables from the South Vietnamese Ambassador Bui Diem in Washington, DC, to his home government in Saigon) and Central Intelligence Agency (which bugged South Vietnamese President Nguyen Van Thieu's office). *"[I am] still in contact with the Nixon entourage, which continues to be the favorite despite the uncertainty provoked by the news of an imminent bombing halt," Ambassador Diem cabled President Thieu on Oct. 28, 1968. "I [explained discreetly to our partisan friends our] firm attitude." The president ordered the Federal Bureau of Investigation to put a wiretap on the embassy's phone and tail one of "our partisan friends," Anna Chennault, the Republican Party's top female fundraiser.*

It didn't take long for the FBI to strike pay dirt. Three days before the election, the bureau sent the White House this wiretap report: "Mrs. Anna Chennault contacted Vietnamese Ambassador Bui Diem and advised him that she had received a message from her boss (not further identified) which her boss wanted her to give personally to the ambassador. She said the message was that the ambassador is to 'hold on, we are gonna win' and that her boss also said, 'Hold on, he understands all of it.'" That day, President Thieu had announced that the South would not send a delegation to Paris, rendering any settlement of the war impossible for the time being and stalling Humphrey's surge in the polls.

1979 (Dec 21) - Younger Joseph A Sachs (brother) passes

Article : [HN00IA][GDrive]

SACKS-Joseph A. Beloved husband of the late Florence. Devoted father of Sanford, Renee Benin and Zachary. Cherished grandfather of Sharon, David. Wendy, Benlamin and Alexander. Dear brother of Eleanor Barr. Service Sunday December 23 at 10:30 a.m. "The Riverside", 76th St. & Amsterdam Ave.

Alexander Sachs notes from FDR Library (at Marist College)

Download list (as of 2020) at : [HE0016][GDrive]

Papers of ALEXANDER SACHS (1874-1973)

The papers were donated to the Library by Charlotte Cramer Sachs (Mrs. Alexander Sachs) in 1985.

The papers consist of correspondence, financial papers, reports, studies, memoranda, minutes, printed material, extracts, charts, tables, statistics, ledgers, speeches and court testimony relating to Alexander Sachs' work as an economist and independent consultant in economic administration, his service as an economic advisor to President Roosevelt and to several government agencies and departments including the National Recovery Administration, the National Policy Committee, the President's Power Pool Conference, the Interstate Oil Compact Commission, the Petroleum Industry War Council, the Office of Strategic Services, Department of Defense, the Federal Reserve Board, the National Industrial Conference Board, the Justice Department and the State Department. Also included are his files relating to his work as an independent economic consultant to major corporations, utilities, railroads and some individuals.

Also included is material on Alexander Sachs' personal interests in philosophy, history, religion, the Middle East, Palestine, atomic energy, international relations and government. Among the subjects included, there is material on agriculture, banking, building, commodities, currency, depression, labor, minerals, oil, politics, public finance, railroads, recovery, stock markets, and taxation.

Alexander Sachs - DESCRIPTION OF THE COLLECTION

This collection consists of Alexander Sachs' office files generated by his work for Walter Meyer, the Lehman Corporation, various government agencies and departments, and his clients. There are some files concerning financial and family matters and non-economic subjects of personal interest to Alexander Sachs including ancient history, the Middle East, science, philosophy and religion.

The papers are arranged in eleven different series, following the filing procedures used in his office. These series are: correspondence files; subject files; reports, studies and memoranda; economic charts and statistics; chronological file; unfinished work and notes; economic extracts; government publications; desiderata; clients file; and financial matters.

Periodically, the office files were culled of inactive files to be sent to storage. These storage files have been reintegrated into the collection.

The series of reports, studies and memoranda was created during the processing of the collection to contain those items which had been water damaged prior to their arrival at the Library. During the water damage and resultant restoration processes, the office file designations for these items were removed.

All of the series are interconnected. For example, although the bulk of the papers relating to one of Mr. Sachs' clients will be in the client's file, correspondence with a company official may be in the correspondence file, a study on the client's type of business may be in the reports, studies and memoranda file, charts for that report may be among the economic charts and statistics, carbon copies of letters from Mr. Sachs to a company official may be in the chronological file, extracts of articles published by the company may be in the economic extracts, and government publications may have been used to compile reports to the company. Some of the related items are cross-referenced.

A small amount of correspondence from Alexander Sachs to Sidney B. Lurie was given to the Library by Mr. Lurie in 1983. These items have been placed in the correspondence file: Lurie, Sidney B.

SACHS, ALEXANDER (1893–1973)

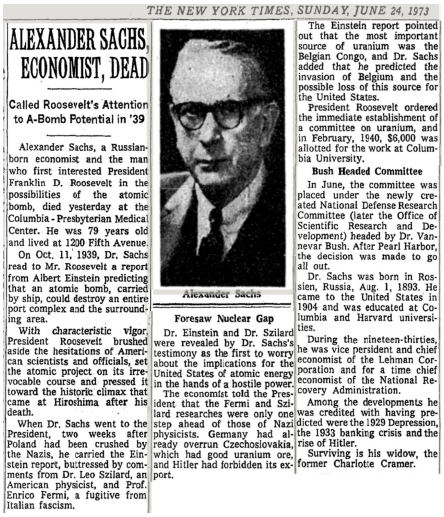
Although Alexander Sachs made his career as an economist, his most important role may have been convincing Franklin D. Roosevelt to fund research into atomic bombs. Born in Lithuania on August 1, 1893, Sachs came to the United States with his family as Jewish refugees in 1904. He graduated from Columbia University in 1912 and subsequently did postgraduate work in philosophy at Harvard, although he did not earn a doctorate. He became an economist with Lehman Brothers, known for his scorn of stock market hype in the 1920s and his disdain for Hoover administration recovery efforts.

Sachs was an acquaintance of **Albert Einstein** and had served President Roosevelt on a number of New Deal projects. He therefore struck Einstein, **Enrico Fermi**, and **Leo Szilard** as the appropriate go-between to explain their atomic theories—and the dangers of other countries developing an atomic bomb—to the president. Sachs' October 11, 1939, visit to the White House led to Roosevelt's forming a series of committees that ultimately approved the Manhattan Project. Sachs also served the war effort as an economic consultant for several government agencies.

His enthusiasm for the atomic bomb paled after the bombing of Hiroshima and Nagasaki. Sachs had expected its first uses to be test detonations that would convince Germany and Japan to surrender. Feeling that the United States had made a moral error in using the bomb on civilians, he became an advocate of nuclear arms control. Sachs died on June 23, 1973, in New York.

Wende Vyborney Feller

1973 (June 23) - Alexander Sachs dies



THE NEW YORK TIMES, SUNDAY, JUNE 24, 1973

ALEXANDER SACHS, ECONOMIST, DEAD

Called Roosevelt's Attention to A-Bomb Potential in '39

Alexander Sachs, a Russian-born economist and the man who first interested President Franklin D. Roosevelt in the possibilities of the atomic bomb, died yesterday at the Columbia-Presbyterian Medical Center. He was 79 years old and lived at 1200 Fifth Avenue.

On Oct. 11, 1939, Dr. Sachs read to Mr. Roosevelt a report from Albert Einstein predicting that an atomic bomb, carried by ship, could destroy an entire port complex and the surrounding area.

With characteristic vigor, President Roosevelt brushed aside the hesitations of American scientists and officials, set the atomic project on its irrevocable course and pressed it toward the historic climax that came at Hiroshima after his death.

When Dr. Sachs went to the President, two weeks after Poland had been crushed by the Nazis, he carried the Einstein report, buttressed by comments from Dr. Leo Szilard, an American physicist, and Prof. Enrico Fermi, a fugitive from Italian fascism.

Alexander Sachs

Foresaw Nuclear Gap

Dr. Einstein and Dr. Szilard were revealed by Dr. Sachs's testimony as the first to worry about the implications for the United States of atomic energy in the hands of a hostile power.

The economist told the President that the Fermi and Szilard researches were only one step ahead of those of Nazi physicists. Germany had already overrun Czechoslovakia, which had good uranium ore, and Hitler had forbidden its export.

The Einstein report pointed out that the most important source of uranium was the Belgian Congo, and Dr. Sachs added that he predicted the invasion of Belgium and the possible loss of this source for the United States.

President Roosevelt ordered the immediate establishment of a committee on uranium, and in February, 1940, $6,000 was allotted for the work at Columbia University.

Bush Headed Committee

In June, the committee was placed under the newly created National Defense Research Committee (later the Office of Scientific Research and Development) headed by Dr. Vannevar Bush. After Pearl Harbor, the decision was made to go all out.

Dr. Sachs was born in Rossien, Russia, Aug. 1, 1893. He came to the United States in 1904 and was educated at Columbia and Harvard universities.

During the nineteen-thirties, he was vice president and chief economist of the Lehman Corporation and for a time chief economist of the National Recovery Administration.

Among the developments he was credited with having predicted were the 1929 Depression, the 1933 banking crisis and the rise of Hitler.

Surviving is his widow, the former Charlotte Cramer.

) (Samogitian: *Raseinė*, Polish: *Rosienie*, Yiddish: ראָסיין) is a city in Lithuania. It is located on the south eastern foothills of the Samogitians highland, some 5 km (3.1 mi) north from the Kaunas–Klaipėda highway. "

ADDITIONAL INFO - HENRY "HARRY" SACHS

1931 (Oct 16) - Alexander Sachs traveling from France to NYC -- Traveled on same ship with Henry ("Harry") Sachs and his family (but they may not have been traveling as a group)

Born Aug 1 1892 ... Alexander Sachs would be age 40 on Aug 1 1932 - Age 39 on Aug 1 1892 - but this form says age 37 ..

It says that this Harry Sachs lives at "**4W 74th Street in New York City** "... Which indeed is the address in his Obituary ... So this is the banker from Goldman Sachs ... (more info on Harry Sachs in additional references of this page).

Harry Sachs, banker - Dies in February 18 of 1933

Full page : [HN00J4][GDrive]

The Brooklyn Daily Eagle (Brooklyn, New York) • 18 Feb 1933, Sat • Page 22

Harry Sachs Dies In Atlantic City; Banker Was 76

Atlantic City, Feb. 18 (AP)—Harry Sachs, 76, of New York, a member of the investment banking firm of Goldman, Sachs & Co., died at the Shelburne Hotel last night. He had been ill for some time with diabetes and complications incidental to his age.

He registered at the hotel four days ago. Several relatives, including his wife, son and daughter, were at the bedside when he died. His body was taken to New York.

Born in Baltimore

Harry Sachs lived at 4 W. 74th St., Manhattan. He was for 40 years a member of the international banking firm of Goldman, Sachs & Co. Recently he had been acting in an advisory capacity, although at one time he was the floor member for the firm on the New York Stock Exchange.

Mr. Sachs was born in Baltimore and came to New York City as a child. Prior to entering the investment field he was in the mercantile business.

No funeral arrangements have been made yet.

SALOON, CABIN, AND STEERAGE ALIENS MUST BE COMPLETELY MANIFESTED.
THIS SHEET IS FOR STEERAGE PASSENGERS.

LIST OR MANIFEST OF ALIEN PASSENGERS FOR THE U. S. IMMIGRATION OFFICER AT PORT OF ARRIVAL.

Required by the regulations of the Secretary of the Treasury of the United States, under Act of Congress approved March 3, 1903, to be delivered to the U. S. Immigration Officer by the Commanding Officer of any vessel having such passengers on board upon arrival at a port in the United States.

S. S. Blücher sailing from Hamburg, 22 January 1904, 790 Arriving at Port of New York February 5th 1904

[HJ0008][GDrive]

1910 - US Census for "Sacks" family

- "Sacks" not "Sachs"
- Younger brother **Alexander Sachs** (born 1892) still has name "Samuel" (not yet changed to "Alexander")
- 38 (or 40?) west 117th street - Right next to 1915 address
- Herman Sack immigrated to the USA in 1901, 3 years before his siblings
- Sadly, mother Sarah must have passed (father "Sundel" is widowed)
- Father here is "Sundel", not "Samuel" ... ???
- Sister "Elinor" is here as "Lena"

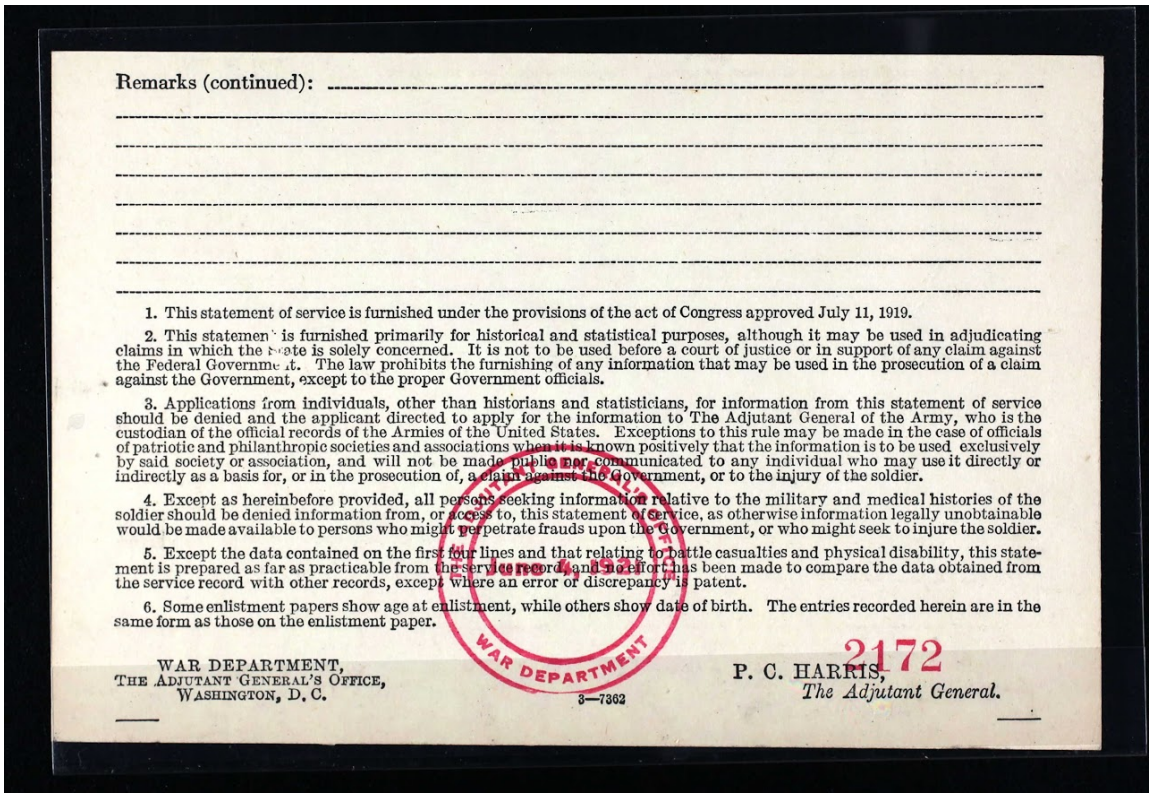
[HG001J][GDrive]



Remarks (continued):

1. This statement of service is furnished under the provisions of the act of Congress approved July 11, 1919.

2. This statement is furnished primarily for historical and statistical purposes, although it may be used in adjudicating claims in which the state is solely concerned. It is not to be used before a court of justice or in support of any claim against the Federal Government. The law prohibits the furnishing of any information that may be used in the prosecution of a claim against the Government, except to the proper Government officials.

3. Applications from individuals, other than historians and statisticians, for information from this statement of service should be denied and the applicant directed to apply for the information to The Adjutant General of the Army, who is the custodian of the official records of the Armies of the United States. Exceptions to this rule may be made in the case of officials of patriotic and philanthropic societies and associations when it is known positively that the information is to be used exclusively by said society or association, and will not be made public nor communicated to any individual who may use it directly or indirectly as a basis for, or in the prosecution of, a claim against the Government, or to the injury of the soldier.

4. Except as hereinbefore provided, all persons seeking information relative to the military and medical histories of the soldier should be denied information from, or access to, this statement of service, as otherwise information legally unobtainable would be made available to persons who might perpetrate frauds upon the Government, or who might seek to injure the soldier.

5. Except the data contained on the first four lines and that relating to battle casualties and physical disability, this statement is prepared as far as practicable from the service record, and no effort has been made to compare the data obtained from the service record with other records, except where an error or discrepancy is patent.

6. Some enlistment papers show age at enlistment, while others show date of birth. The entries recorded herein are in the same form as those on the enlistment paper.

WAR DEPARTMENT,
THE ADJUTANT GENERAL'S OFFICE,
WASHINGTON, D. C.

Charlotte Cramer Sachs (born 1907)

https://sova.si.edu/record/NMAH.AC.0878

2019-smithsonial-online-virtual-archives-charlotte-cramer-sachs-papers.pdf

Biographical / Historical

Charlotte Cramer Sachs *was born in Berlin, Germany on September 27, 1907. Her father,* ***Hans Siegfried Cramer,*** *worked as a businessman for a successful grain import and export company whose innovative enterprises included the import of soy beans from Eastern Europe. In 1903, Hans married Gertrud Bruck, one of the first women to attain her Abitur, somewhat similar to an American high school diploma, at age eighteen. Bruck's formal education ended there, as her wish to attend university was thwarted by her father Adalbert, a judge who insisted that she remain at home. The couple settled in Berlin and had two children—Frederick H., born March 2, 1906, and Charlotte. From 1913 to 1924 The Cramers lived in the Berlin Dahlem suburb occupying "Haus Cramer," a villa built in 1912 to their specifications by German architect Hermann Muthesius.*

On September 12, 1924, Cramer Sachs married Donald Samuels, a top executive of the Manhattan Shirt Company and moved to New York from England where their daughter Eleanor was born on June 11, 1926. Several years later, the couple divorced. Mother and daughter lived together in London for a few years before moving back to New York around 1936. Charlotte's parents relocated to New York at the same time, after a brief stay in London following their flight from Berlin after Hitler's rise to power. ***In August 1945, Charlotte Cramer married Alexander Sachs, a leading economist who had introduced Albert Einstein to President Franklin Delano Roosevelt and acted as advisor to the President.***

Although she established her business career in America, Cramer Sachs retained fond memories of the house and extensive grounds in Dahlem. In 1977 she composed the song "A Salute to Berlin" to commemorate the designation of Haus Cramer as one of the city's historic landmarks. In 2000, she donated a painted portrait of herself from the time she had lived in Haus Cramer to the villa's new owner, Stanford University. The house retains additional significance in the context of this collection because Cramer Sachs credited its wine cellar—unusual in that it provided a separate, climate controlled environment for red and white wines—as an inspiration for her line of custom-built, vibration-free wine storage devices, which would later make Cramer Products Company a household name among wine connoisseurs.

While she did not attend university her pursuit of learning continued throughout her life as she studied poetry, musical composition, and the fine arts. Cramer Sachs often told her niece, Lilian Randall, that she wished she had received further education, although her public art exhibitions, poetry awards, numerous original songs, the establishment of Crambruck Press (her own publishing company), as well as language fluency in French, English, and German, are testaments to this inventor's intellectual curiosity and development. Evidence of Cramer Sachs's entrepreneurial spirit surfaced in her early thirties with her first patent: Improvements in Combined Key and Flashlight, July 16, 1940, patent number 2,208,498.

In 1940, Cramer Sachs completed courses from the New York Institute of Dietetics, an effort spurred by the onset of her daughter's diabetes. With financial assistance from her parents in the early 1940s, Cramer Sachs developed Joy Products prepared mixes, marking the beginning of a successful career in inventing. "We were a pioneer in that field," said Cramer Sachs of her baking mix manufacturing company, an operation that consisted of a Bronx neighborhood factory employing ninety workers. The enterprise began with corn muffin and popover mixes and expanded into frostings, puddings, and breads. Newspaper clippings from the time promoted Joy packaged mixes as ideal gifts for "the boys overseas" who were in locations where it was "impossible to get together the makings of a cake." Cramer Sachs refused an early offer to sell her mix formulas which were subsequently copied and exploited by larger, more powerful companies. Joy Products, whose name was chosen to express the inventor's delight in creativity, remained in business as a modest one-woman operation for over twenty years before succumbing to competition.

Cramer Sachs created another highly successful invention, the specialty wine cabinet, more than twenty years after she founded Joy Products. In addition to her memories of visits with her father to the wine cellar in her family's German villa, further motivation came from an interest—though she hardly drank it at all—in wine and recognition that "standard cooling and refrigerating appliances [were] too cold for wines." Reportedly, Cramer Sachs "started looking for [an appropriate device] and could not find one," and thus the impetus to invent took shape. The "Modern Wine Cellar," 1966, was an early example of over twenty wine-related inventions, most of them storage devices. A mention of her product in Grossman's Guide to Wines, Spirits, and Beers, increased demand among wine lovers and may have prompted Cramer Sachs to state that she "should find a good market" for her newest invention line. Testimony from David H. Wollins, a successful New York lawyer and customer of Cramer Sachs, lauded the cabinet as "the finest home wine storage system in the world." She framed his letter and hung it in her office at 381 South Park Avenue, her base operation where she employed one or two part-time helpers from the 1960s until her death in 2004.

The inventor took great joy in music, expressed in her own numerous compositions and her creation of the games "Domi-Notes" and "Musicards" in 1961 and 1969. Her fondness for music also prompted the expansion of her specialty cabinets to include temperature and humidity controlled devices for storing a variety of items, most notably the "Well Tempered Cabinet for Musical Instruments," which Cramer Sachs first designed for legendary violinist Isaac Stern. Soon the inventor began producing similar cabinets for the storage of cigars, furs, and documents.

Described by her niece as "shy with people but a great admirer of talent, intellect, and humanity," Cramer Sachs also "harbored a great love for animals." She invented several pet accessories in the early 1950s, including: "Watch-Dog," a dog collar with a time piece; "Bonnie Stand," a holder fashioned to accommodate disposable food bowls; and "Guidog," an early version of a retractable dog leash.

In 1972, Cramer Sachs suffered the loss of her only child, Eleanor, and in the summer of the next year her husband Alexander passed away. She continued her "business of creating new product ideas" for the remainder of her life. The most recent invention materials represented in the collection are those for the "Conservator" from 2002, a temperature and humidity controlled device with compartments to store a variety of items. In her last telephone conversation with her niece, on March 10, 2004, Cramer Sachs expressed her hope that she would feel "strong enough to get to the office the next day or so." The inventor died the following day at the age of 96.

Patents issued to Charlotte Cramer Sachs:

United States Patent: 2,208,498, "Combined Key and Flashlight," July 16, 1940

United States Patent: 2,509,423, "Wedge Heel Shoe," May 30, 1950

United States Patent: 2,808,191, "Lap Tray," October 1, 1957

United States Patent: Des. 363,618, "Cabinet," October 31, 1995

Saved Wikipedia (Dec 30, 2020) - Paul Sagan

[HK004K][GDrive]

Born 1959 (age 60–61)

Nationality American

Alma mater Medill School of Journalism

Occupation Business executive

Employer General Catalyst Partners

Paul Sagan (born 1959) is an American businessman and managing partner at General Catalyst Partners.[1] A three-time Emmy award winner for broadcast journalism in New York,[2] Sagan began his career at WCBS-TV as a news writer and news director.[3] Joining Time Warner to design and launch NY1, in 1995 he was named president and editor of new media at Time Inc.[4] Sagan joined Akamai Technologies in 1998,[5] becoming CEO in 2005.[5] In 2014, he became a venture capitalist at General Catalyst Partners.[1] He became chairman of the Massachusetts Board of Elementary and Secondary Education in 2015.[6]

Career[edit]

Media and news[edit]

Upon graduating from the Medill School of Journalism at Northwestern University, Sagan began his career at WCBS-TV as a news writer. He was named news director in 1987.[3]

In 1991, he joined Time Warner to design and launch NY1. In 1995 he was named president and editor of new media at Time Inc.,[4] a position he held until 1997.

From 1997 to 1998 Sagan served as senior adviser to the World Economic Forum.

Akamai[edit]

Sagan joined Akamai Technologies in October 1998 as chief operating officer, became president the following year[5] in 1999.[1]

He was elected to the Akamai board of directors in January 2005,[5] and would serve as the executive vice chairman of Akamai Technologies.[7]

He became CEO in April 2005.[5] During his tenure, he oversaw a number of acquisitions.[1] He was succeeded as Akamai CEO by Akamai co-founder Tom Leighton on January 1, 2013.[8]

General Catalyst[edit]

In January 2014, he became a venture capitalist at General Catalyst Partners in Cambridge, Massachusetts.[1] He became a partner at the firm.[1][9] He kept his role as vice chairman of Akamai's board.[9][10]

Moderna[edit]

Throughout the COVID-19 pandemic, Sagan served as Senior Advisor and Executive-in-Residence at Moderna as a member of the Board of directors working on vaccines.[11]

Boards[edit]

He is a member of the board of directors of Akamai,[7]VMware, Inc., and the not-for-profit ProPublica,[12] of which he named chairman in December 2016.[13] He is also a trustee of his alma mater, Northwestern University.[12]

Previously, he was a member of the board of directors of Datto Inc.[14], Dow Jones & Company,[15]Digitas,[16] EMC Corporation,[17] L2, Inc.,[17] Maven Networks,[18] OpenMarket,[19] FutureTense, Inc.,[20]and VDONet Corp.[21] before each company was sold. He also served for a period of time on the boards of Experience, Inc.[22] iRobot Corp. and Medialink Worldwide, Inc.[23] He resigned from the iRobot board in June 2015.[24]

Committees and public positions[edit]

Sagan was appointed by President Barack Obama to the President's National Security Telecommunications Advisory Committee in 2010 and served until 2017..[25]

Governor Charlie Baker appointed Sagan to be chairman of the Massachusetts Board of Elementary and Secondary Education in 2015.[6] In 2017, there was a controversy when a state investigation found that he had donated $500,000 to the nonprofit Families for Excellent Schools, a charter school advocacy group that had been fined for hiding donors' identities in 2016, and which had been involved in a ballot question the year before. Sagan defended his decision to keep the donation private.[26][27][28] The Massachusetts Teachers Association and some others called for Sagan to be fired from his chairmanship for the donation, but the Governor had defended Sagan. [29][30]As of 2018, Sagan remained chair of the Board of Elementary and Secondary Education.[31]

Honors[edit]

He is a three-time Emmy award winner for broadcast journalism in New York.[2] He became a fellow of the American Academy of Arts and Sciences in 2008.[32] In 2009 Sagan was named the Ernst & YoungEntrepreneur of the Year award in the technology category.[33] In 2008 he was named as a member of the Knight Commission on the Information Needs of Communities in a Democracy.[34]

Signature

Jonas Edward Salk (/sɔːlk/; born Jonas Salk; October 28, 1914 – June 23, 1995) was an American virologist and medical researcher who developed one of the first successful polio vaccines. He was born in New York City and attended the City College of New York and New York University School of Medicine.[2]

In 1947, Salk accepted a professorship in the School of Medicine at the University of Pittsburgh. It was there that he undertook a project to determine the number of different types of poliovirus, starting in 1948. For the next seven years Salk devoted himself towards developing a vaccine against polio.

Salk was immediately hailed as a "miracle worker" when the vaccine's success was first made public in April 1955, and chose to not patent the vaccine or seek any profit from it in order to maximize its global distribution.[2] An immediate rush to vaccinate began in both the United States and around the world. Many countries began polio immunization campaigns using Salk's vaccine, including Canada, Sweden, Denmark, Norway, West Germany, the Netherlands, Switzerland, and Belgium. By 1959, the Salk vaccine had reached about 90 countries.[3] Less than 25 years later, domestic transmission of polio had been completely eliminated in the United States.

In 1963, Salk founded the Salk Institute for Biological Studies in La Jolla, California, which is today a center for medical and scientific research. He continued to conduct research and publish books in his later years, focusing in his last years on the search for a vaccine against HIV. Salk also campaigned vigorously for mandatory vaccination throughout the rest of his life, calling the universal vaccination of children against disease a "moral commitment".[4] Salk's personal papers are today stored in Geisel Library at the University of California, San Diego.[5][6]

[...]

Early life and education

Jonas Salk was born in New York City to Daniel and Dora (née Press) Salk. His parents were Ashkenazi Jewish; Daniel was born in New Jersey to immigrant parents and Dora, who was born in Minsk, emigrated when she was twelve.[7][8] Salk's parents did not receive extensive formal education.[2] Jonas had two younger brothers, Herman and Lee, a renowned child psychologist.[10] The family moved from East Harlem to 853 Elsmere Place, the Bronx,[11] with some time spent in Queens at 439 Beach 69th Street, Arverne.[12]

When he was 13, Salk entered Townsend Harris High School, a public school for intellectually gifted students. Named after the founder of City College of New York (CCNY), it was, wrote his biographer, Dr. David Oshinsky, "a launching pad for the talented sons of immigrant parents who lacked the money—and pedigree—to attend a top private school." In high school "he was known as a perfectionist ... who read everything he could lay his hands on," according to one of his fellow students.[13] Students had to cram a four-year curriculum into just three years. As a result, most dropped out or flunked out, despite the school's motto "study, study, study." Of the students who graduated, however, most had the grades to enroll in CCNY, noted for being a highly competitive college.[14]:96

Education

Salk enrolled in CCNY, from which he earned a Bachelor of Science degree in chemistry in 1934.[15] Oshinsky writes that "for working-class immigrant families, City College represented the apex of public higher education. Getting in was tough, but tuition was free. Competition was intense, but the rules were fairly applied. No one got an advantage based on an accident of birth."[14]

At his mother's urging, he put aside aspirations of becoming a lawyer and instead concentrated on classes necessary for admission to medical school. However, according to Oshinsky, the facilities at City College were "barely second rate." There were no research laboratories. The library was inadequate. The faculty contained few noted scholars. "What made the place special," he writes, "was the student body that had fought so hard to get there... driven by their parents.... From these ranks, of the 1930s and 1940s, emerged a wealth of intellectual talent, including more Nobel Prize winners—eight—and PhD recipients than any other public college except the University of California at Berkeley." Salk entered CCNY at the age of 15, a "common age for a freshman who had skipped multiple grades along the way."[14]:98

As a child, Salk did not show any interest in medicine or science in general. He said in an interview with the Academy of Achievement,[16] "As a child I was not interested in science. I was merely interested in things human, the human side of nature, if you like, and I continue to be interested in that."

Medical school

After City College, Salk enrolled in New York University to study medicine. According to Oshinsky, NYU based its modest reputation on famous alumni, such as Walter Reed, who helped conquer yellow fever. Tuition was "comparatively low, better still, it did not discriminate against Jews... while most of the surrounding medical schools—Cornell, Columbia, University of Pennsylvania, and Yale—had rigid quotas in place." Yale, for example, accepted 76 applicants in 1935 out of a pool of 501. Although 200 of the applicants were Jewish, only five got in.[14]:98 During his years at New York University Medical School, Salk worked as a laboratory technician during the school year and as a camp counselor in the summer.[15]

*[NOTE : **Dr. Alice E. Moore (born 1908)** was a research peer and mentor-ee of **Dr. Thomas Francis Jr. (born 1900)** at the New York University Medical School (in the Dept. of Bacteriology) from 1938 to 1942, after which time she took a role at the Rockefeller Institute]*

During Salk's medical studies, he stood out from his peers, according to Bookchin, "not just because of his continued academic prowess—he was Alpha Omega Alpha, the Phi Beta Kappa Society of medical education—but because he had decided he did not want to practice medicine." Instead, he became absorbed in research, even taking a year off to study biochemistry. He later focused more of his studies on bacteriology, which had replaced medicine as his primary interest. He said his desire was to help humankind in general rather than single patients.[13] "It was the laboratory work, in particular, that gave new direction to his life."[14]

Salk has said: "My intention was to go to medical school, and then become a medical scientist. I did not intend to practice medicine, although in medical school, and in my internship, I did all the things that were necessary to qualify me in that regard. I had opportunities along the way to drop the idea of medicine and go into science. At one point at the end of my first year of medical school, I received an opportunity to spend a year in research and teaching in biochemistry, which I did. And at the end of that year, I was told that I could, if I wished, switch and get a Ph.D. in biochemistry, but my preference was to stay with medicine. And, I believe that this is all linked to my original ambition, or desire, which was to be of some help to humankind, so to speak, in a larger sense than just on a one-to-one basis."[17]

Concerning his last year of medical school, Salk said: "I had an opportunity to spend time in elective periods in my last year in medical school, in a laboratory that was involved in studies on influenza. The influenza virus had just been discovered about a few years before that. And, I saw the opportunity at that time to test the question as to whether we could destroy the virus infectivity and still immunize. And so, by carefully designed experiments, we found it was possible to do so."[18]

Postgraduate research and early laboratory work

In 1941, during his postgraduate work in virology, Salk chose a two-month elective to work in the [Dr. Thomas Francis Jr. (born 1900)]' laboratory at the University of Michigan. Francis had recently joined the faculty of the medical school after working for the Rockefeller Foundation, where he had discovered the type B influenza virus. According to Bookchin, "the two-month stint in Francis's lab was Salk's first introduction to the world of virology—and he was hooked."[13]:25 After graduating from medical school, Salk began his residency at New York's prestigious[14] Mount Sinai Hospital, where he again worked in Francis's laboratory.[14] **Salk then worked at the University of Michigan School of Public Health with Francis, on an army-commissioned project in Michigan to develop an influenza vaccine. He and Francis eventually perfected a vaccine that was soon widely used at army bases, where Salk discovered and isolated one of the strains of influenza that was included in the final vaccine.**[13]:26

Polio research[edit]

Further information: Polio and Polio vaccine

President Franklin D. Roosevelt meeting with Basil O'Connor

In 1947, Salk became ambitious for his own lab and was granted one at the University of Pittsburgh School of Medicine, but the lab was smaller than he had hoped and he found the rules imposed by the university restrictive.[19] In 1948, Harry Weaver, the director of research at the National Foundation for Infantile Paralysis, contacted Salk. He asked Salk to find out if there were more types of polio than the three then known, offering additional space, equipment and researchers. For the first year he gathered supplies and researchers including Julius Youngner, Byron Bennett, L. James Lewis, and secretary Lorraine Friedman joined Salk's team, as well.[20][21] As time went on, Salk began securing grants from the Mellon family and was able to build a working virology laboratory.[13] He later joined the National Foundation for Infantile Paralysis's polio project established by President Franklin D. Roosevelt.[13][22]

Extensive publicity and fear of polio led to much increased funding, $67 million by 1955, but research continued on dangerous live vaccines.[23][14]:85–87 **Salk decided to use the safer 'killed' virus, instead of weakened forms of strains of polio viruses like the ones used contemporaneously by Albert Sabin, who was developing an oral vaccine.**[24]

After successful tests on laboratory animals, on July 2, 1952, assisted by the staff at the D.T. Watson Home for Crippled Children, Salk injected 43 children with his killed-virus vaccine. A few weeks later, Salk injected children at the Polk State School for the retarded and feeble-minded. He vaccinated his own children in 1953.[25][26] **In 1954 he tested the vaccine on about one million children, known as the polio pioneers. The vaccine was announced as safe on April 12, 1955.**[23][22][27][28][29]

Salk in 1955 at the University of Pittsburgh

Magazine photo of Jonas Salk to O'Neill, "the most elaborate program of its kind in history, involving 20,000 physicians and public health officers, 64,000 school personnel, and 220,000 volunteers,"[23] with over 1.8 million school children participating in the trial.[30] A 1954 Gallup poll showed that more Americans knew about the polio field trials than could give the full name of the President.

March of Dimes poster circa 1957

The project became large, involving 100 million contributors to the March of Dimes, and 7 million volunteers.[23][31]:54 The foundation allowed itself to go into debt to finance the final research required to develop the Salk vaccine.[32] Salk worked incessantly for two-and-a-half years.[23][33]

Salk's inactivated polio vaccine was the first vaccine for the disease; it came into use in 1955.[34][35] It is on the World Health Organization's List of Essential Medicines, the safest and most effective medicines needed in a health system.[36]

Becoming a public figure[edit]

Celebrity versus privacy[edit]

With David Ben-Gurion in Jerusalem, 1959

Salk preferred not to have his career as a scientist affected by too much personal attention, as he had always tried to remain independent and private in his research and life, but this proved to be impossible. "Young man, a great tragedy has befallen you—you've lost your anonymity", the television personality Ed Murrow said to Salk shortly after the onslaught of media attention.[37] When Murrow asked him, "Who owns this patent?", Salk replied, "Well, the people I would say. There is no patent. Could you patent the sun?"[38] The vaccine is calculated to be worth $7 billion had it been patented.[39] However, lawyers from the National Foundation for Infantile Paralysis did look into the possibility of a patent, but ultimately determined that the vaccine was not a patentable invention because of prior art.[40]

Salk served on the board of directors of the John D. and Catherine T. MacArthur Foundation.[41]

Author Jon Cohen noted, "Jonas Salk made scientists and journalists alike go goofy. As one of the only living scientists whose face was known the world over, Salk, in the public's eye, had a superstar aura. Airplane pilots would announce that he was on board and passengers would burst into applause. Hotels routinely would upgrade him into their penthouse suites. A meal at a restaurant inevitably meant an interruption from an admirer, and scientists approached him with drop-jawed wonder as though some of the stardust might rub off."[42]

For the most part, however, Salk was "appalled at the demands on the public figure he has become and resentful of what he considers to be the invasion of his privacy", wrote The New York Times, a few months after his vaccine announcement.[29] The Times article noted, "at 40, the once obscure scientist ... was lifted from his laboratory almost to the level of a folk hero." He received a presidential citation, a score of awards, four honorary degrees, half a dozen foreign decorations, and letters from thousands of fellow citizens. His alma mater, City College of New York, gave him an honorary degree as Doctor of Laws. But "despite such very nice tributes", The New York Times wrote, "Salk is profoundly disturbed by the torrent of fame that has descended upon him. ... He talks continually about getting out of the limelight and back to his laboratory ... because of his genuine distaste for publicity, which he believes is inappropriate for a scientist."[29]

During a 1980 interview, 25 years later, he said, "It's as if I've been a public property ever since, having to respond to external, as well as internal, impulses. ... It's brought me enormous gratification, opened many opportunities, but at the same time placed many burdens on me. It altered my career, my relationships with colleagues; I am a public figure, no longer one of them."[37]

Maintaining his individuality[edit]

"If Salk the scientist sounds austere", wrote The New York Times, "Salk the man is a person of great warmth and tremendous enthusiasm. People who meet him generally like him." A Washington newspaper correspondent commented, "He could sell me the Brooklyn Bridge, and I never bought anything before." Award-winning geneticist Walter Nelson-Rees called him "a renaissance scientist: brilliant, sophisticated, driven ... a fantastic creature."[43]:127

He enjoys talking to people he likes, and "he likes a lot of people", wrote the Times. "He talks quickly, articulately, and often in complete paragraphs." And "He has very little perceptible interest in the things that interest most people—such as making money." That belongs "in the category of mink coats and Cadillacs —unnecessary", he said.[29]

Establishing the Salk Institute[edit]

The Salk Institute at La Jolla

In the years after Salk's discovery, many supporters, in particular the National Foundation, "helped him build his dream of a research complex for the investigation of biological phenomena 'from cell to society'."[44] Called the Salk Institute for Biological Studies, it opened in 1963 in the San Diego neighborhood of La Jolla. Salk believed that the institution would help new and upcoming scientists along in their careers, as he said himself, "I thought how nice it would be if a place like this existed and I was invited to work there."[citation needed]

In 1966, Salk described his "ambitious plan for the creation of a kind of Socratic academy where the supposedly alienated two cultures of science and humanism will have a favorable atmosphere for cross-fertilization."[45] Author and journalist Howard Taubman explained:

Although he is distinctly future-oriented, Dr. Salk has not lost sight of the institute's immediate aim, which is the development and use of the new biology, called molecular and cellular biology, described as part physics, part chemistry and part biology. The broad-gauged purpose of this science is to understand man's life processes.

There is talk here of the possibility, once the secret of how the cell is triggered to manufacture antibodies is discovered, that a single vaccine may be developed to protect a child against many common infectious diseases. There is speculation about the power to isolate and perhaps eliminate genetic errors that lead to birth defects.

Dr. Salk, a creative man himself, hopes that the institute will do its share in probing the wisdom of nature and thus help enlarge the wisdom of man. For the ultimate purpose of science, humanism and the arts, in his judgment, is the freeing of each individual to cultivate his full creativity, in whichever direction it leads. ... As if to prepare for Socratic encounters such as these, the institute's architect, Louis Kahn, has installed blackboards in place of concrete facings on

the walls along the walks.[45]

The New York Times, in a 1980 article celebrating the 25th anniversary of the Salk vaccine, described the current workings at the facility:

At the institute, a magnificent complex of laboratories and study units set on a bluff overlooking the Pacific, Dr. Salk holds the titles of founding director and resident fellow. His own laboratory group is concerned with the immunologic aspects of cancer and the mechanisms of autoimmune disease, such as multiple sclerosis, in which the immune system attacks the body's own tissues.[37]

In an interview about his future hopes at the institute, he said, "In the end, what may have more significance is my creation of the institute and what will come out of it, because of its example as a place for excellence, a creative environment for creative minds."

Francis Crick, codiscoverer of the structure of the DNA molecule, was a leading professor at the institute until his death in 2004.

The institute also served as the basis for Bruno Latour and Steve Woolgar's 1979 book Laboratory Life: The Construction of Scientific Facts.[46]

AIDS vaccine work[edit]

Beginning in the mid-1980s, Salk engaged in research to develop a vaccine for AIDS. He cofounded The Immune Response Corporation (IRC) with Kevin Kimberlin and patented Remune, an immunologic therapy, but was unable to secure liability insurance for the product.[47] The project was discontinued in 2007, twelve years after Salk's death.[citation needed]

Salk's "biophilosophy"[edit]

Jonas Salk during a 1988 Centers for Disease Control visit

In 1966, The New York Times referred to him as the "Father of Biophilosophy." According to Times journalist and author Howard Taubman, "he never forgets ... there is a vast amount of darkness for man to penetrate. As a biologist, he believes that his science is on the frontier of tremendous new discoveries; and as a philosopher, he is convinced that humanists and artists have joined the scientists to achieve an understanding of man in all his physical, mental and spiritual complexity. Such interchanges might lead, he would hope, to a new and important school of thinkers he would designate as biophilosophers."[45] Salk told his cousin, Joel Kassiday, at a meeting of the Congressional Clearinghouse on the Future on Capitol Hill in 1984 that he was optimistic that ways to prevent most human and animal diseases would eventually be developed. Salk said people must be prepared to take prudent risks, since "a risk-free society would become a dead-end society" without progress.

Salk describes his "biophilosophy" as the application of a "biological, evolutionary point of view to philosophical, cultural, social and psychological problems." He went into more detail in two of his books, Man's Unfolding, and The Survival of the Wisest. In an interview in 1980, he described his thoughts on the subject, including his feeling that a sharp rise and an expected leveling off in the human population would take place and eventually bring a change in human attitudes:

I think of biological knowledge as providing useful analogies for understanding human nature. ... People think of biology in terms of such practical matters as drugs, but its contribution to knowledge about living systems and ourselves will in the future be equally important. ... In the past epoch, man was concerned with death, high mortality; his attitudes were antideath, antidisease", he says. "In the future, his attitudes will be expressed in terms of prolife and prohealth. The past was dominated by death control; in the future, birth control will be more important. These changes we're observing are part of a natural order and to be expected from our capacity to adapt. It's much more important to cooperate and collaborate. We are the co-authors with nature of our destiny.[37]

His definition of a "biophilosopher" is "Someone who draws upon the scriptures of nature, recognizing that we are the product of the process of evolution, and understands that we have become the process itself, through the emergence and evolution of our consciousness, our awareness, our capacity to imagine and anticipate the future, and to choose from among alternatives."[48]

Just prior to his death, Salk was working on a new book along the theme of biophilosophy, privately reported to be titled Millennium of the Mind.

Personal life[edit]

The day after his graduation from medical school in 1939, Salk married Donna Lindsay, a master's candidate at the New York College of Social Work. David Oshinsky writes that Donna's father, Elmer Lindsay, "a wealthy Manhattan dentist, viewed Salk as a social inferior, several cuts below Donna's former suitors." Eventually, her father agreed to the marriage on two conditions: first, Salk must wait until he could be listed as an official M.D. on the wedding invitations, and second, he must improve his "rather pedestrian status" by giving himself a middle name."[14]:99

They had three children: Peter (who also became a physician and is now a part-time professor of infectious diseases at the University of Pittsburgh),[25][26] Darrell, and Jonathan Salk. In 1968, they divorced and, in 1970, Salk married French painter Françoise Gilot.

Jonas Salk died from heart failure at the age of 80 on June 23, 1995, in La Jolla,[49] and was buried at El Camino Memorial Park in San Diego.[50]

Honors and recognition[edit]

- 1955, one month after the vaccine announcement, he was honored by the Commonwealth of Pennsylvania, where he was given their "highest award for services" by Governor George M. Leader, Meritorious Service Medal, where the governor added,

... in recognition of his 'historical medical' discovery ... Dr. Salk's achievement is meritorious service of the highest magnitude and dimension for the commonwealth, the country and mankind." The governor, who had three children, said that "as a parent he was 'humbly thankful to Dr. Salk,' and as Governor, 'proud to pay him tribute'.[51]

- 1955, City University of New York creates the Salk Scholarship fund which it awards to multiple outstanding pre-med students each year
- 1956, awarded the Lasker Award
- 1957, the Municipal Hospital building, where Salk conducted his polio research at the University of Pittsburgh, is renamed Jonas Salk Hall and is home to the university's School of Pharmacy and Dentistry.[52]
- 1958, awarded the James D. Bruce Memorial Award

Salk's bronze bust in the Polio Hall of Fame

- 1958, elected to the Polio Hall of Fame, which was dedicated in Warm Springs, Georgia
- 1975, awarded the Jawaharlal Nehru Award and the Congressional Gold Medal
- 1976, awarded the Academy of Achievement's Golden Plate Award[53]
- 1976, named the Humanist of the Year by the American Humanist Association
- 1977, awarded the Presidential Medal of Freedom from President Jimmy Carter, with the following statement accompanying the medal:

Because of Doctor Jonas E. Salk, our country is free from the cruel epidemics of poliomyelitis that once struck almost yearly. Because of his tireless work, untold hundreds of thousands who might have been crippled are sound in body today. These are Doctor Salk's true honors, and there is no way to add to them. This Medal of Freedom can only express our gratitude, and our deepest thanks.

- 1981, decorated by the Italian government on January 3 as a Grand Officer of the Order of Merit of the Italian Republic[54]
- 1996, the March of Dimes Foundation created an annual $250,000 cash "Prize" to outstanding biologists as a tribute to Salk.[55]
- 2006, the United States Postal Service issued a 63-cent Distinguished Americans series postage stamp in his honor.
- 2007, California Governor Arnold Schwarzenegger and First Lady Maria Shriver inducted Salk into the California Hall of Fame.[56]
- 2009, BBYO boys chapter chartered in his honor in Scottsdale, Arizona, Named "Jonas Salk AZA #2357"
- Schools in Mesa, Arizona; Spokane, Washington; Tulsa, Oklahoma; Bolingbrook, Illinois; Levittown, New York; Old Bridge, New Jersey; Merrillville, Indiana; Sacramento, California ; and Mira Mesa, California ; are named after him.
- 2012, October 24, in honor of his birthday, has been named "World Polio Day", and was originated by Rotary International over a decade earlier.[57]
- 2014, On the 100th anniversary of Salk's birth, a Google Doodle was created to honor the physician and medical researcher. The doodle shows happy and healthy children and adults playing and going about their lives with two children hold up a sign saying, "Thank you, Dr. Salk!"[58][59]

Documentary films[edit]

- In early 2009, the American Public Broadcasting Service aired its new documentary film, American Experience: The Polio Crusade.[20] The documentary, available on DVD, can also be viewed online at PBS's website.
- On April 12, 2010, to help celebrate the 55th anniversary of the Salk vaccine, a new 66-minute documentary, The Shot Felt 'Round the World, had its world premiere. Directed by Tjardus Greidanus[60] and produced by Laura Davis,[61] the documentary was conceived by Hollywood screenwriter and producer Carl Kurlander to bring "a fresh perspective on the era."[62]
- In 2014, actor and director Robert Redford, who was once struck with a mild case of polio when he was a child, directed a documentary about the Salk Institute in La Jolla.[63]
- In Chapter 10 of the 2018 season of Genius Michael McElhatton portrays Salk in a short cameo where he is on a date with Françoise Gilot.[64]

Salk's book publications[edit]

Werner Schäfer (* 9. März 1912 in Herne-Wanne, Westfalen; † 25. April 2000 in Tübingen) war ein deutscher Tiermediziner und Virologe, der in Tübingen in den Nachkriegsjahren eine Schule für Virologie begründete.

Werner Schäfer (veterinarian)

Werner Schäfer (born March 9, 1912 in Herne-Wanne, Westphalia, † April 25, 2000 in Tübingen) was a German veterinarian and virologist who founded a school for virology in Tübingen in the post-war years.

Life

Schäfer graduated from high school in Korbach in 1931 and then studied veterinary medicine at the University of Gießen. In 1938 he received his doctorate from Hugo Keller (on the concentration of hydrogen ions in various organs in cattle). He became an assistant at the Institute for Veterinary Hygiene and Animal Diseases with Karl Beller and began to turn to virology. At the beginning of the Second World War he was on a research trip to East Africa and was interned there. After an exchange of prisoners, he was a veterinary officer on the Eastern Front and later at the Reich Research Institute Insel Riems. After the war he worked as a resident veterinarian in Usseln before Adolf Butenandt brought him to the Max Planck Institute for Biochemistry in Tübingen as head of the virology department. From 1954 onwards a Max Planck Institute for Virus Research was established in Tübingen (founded by Gerhard Schramm and Hans Friedrich-Freksa [1906–1973]), at which Schäfer stayed for the rest of his career.

Schäfer first examined influenza viruses using the example of avian influenza, which he discovered to be related to the influenza A virus. From the mid-1960s he turned to retroviruses, which at the time were known to cause cancer (leukemia), and research into which began with the emergence of AIDS in the 1980s.

Prizes and awards

In 1991 he received the Robert Koch Medal, 1957 the Carus Medal, 1978 the Paul Ehrlich and Ludwig Darmstaedter Prize, 1972 the Aronson Prize and 1962 the Emil von Behring Prize. He was a Fellow of the Royal Society of Medicine (1959) and a member of the Leopoldina (1969). He was an honorary doctor of the University of Veterinary Medicine Hannover (1972), honorary member of the German Society for Hygiene and Microbiology and the Society for Virology.

[**Prof. Rudolf Rott (born 1926)**] is one of his students.

Life

After graduating from high school in 1931, S. studied humanist. State high school in Korbach (Hesse) at the Univ. Pouring veterinary medicine. After graduating as Dr. med. vet. In 1938 with Hugo Keller (research on the hydrogen ion concentration of various organs and tissues of cattle) he accepted an assistant position in the local institute for veterinary hygiene and animal diseases with Karl Beller. Here he began to deal with virus-related animal diseases. When the war broke out, he was on a research trip to East Africa. This was followed by internment, returning home via a prisoner exchange and military service as a veterinary officer on the Eastern Front and at the "Reich Research Institute Insel Riems". After the end of the war, S. ran a veterinary practice in Usseln (Waldeck). In 1948 he was called by → Adolf Butenandt (1903–95) as head of the virology department at the MPI for Biochemistry in Tübingen.

The MPI for Virus Research was founded here in 1954 under the direction of S., → Gerhard Schramm (1910–69) and → Hans Friedrich-Freksa (1906–73). S., whose work quickly found worldwide recognition, initially dealt with a group of viruses, which include the causative agents of influenza, measles and mumps. He obtained the pure representation of the virus particles, the elucidation of their fine structure and important insights into the reproduction mechanisms. The discovery of the close relationship between the classic avian influenza virus and the influenza A virus in humans was of great importance. **He derived the hypothesis that viruses occasionally change host and that new flu epidemics may have their origin in animals that live closely with humans.** This idea was later confirmed several times, e.g. B. in the epidemic of the Hong Kong flu in 1997. The elucidation of the virus structure made it possible to isolate those components from the virus particles that are particularly important for the infection process. It turned out that such preparations are excellent for immunizations. Because they are well tolerated, they are widely used today for vaccination against influenza and measles.

In 1952, at S.'s instigation, the "Federal Research Center for Virus Diseases of Animals" was established in Tübingen. Employees and students were appointed to professorships in virology or held senior positions in the healthcare sector. S. established a new era of virology in Germany in the post-war years. In the mid-1960s, the focus of his research changed. The interest now turned to the retroviruses, a class of pathogens that cause leukemia and immune deficiencies. Molecular and cell-biological aspects of virus replication were worked on intensively and new approaches for the immunotherapy of these diseases were developed, which were received with great interest in medicine. S. was one of the most important virologists of his generation and contributed significantly to German research regaining international importance after the war. |

Awards

Carus Medal d. Leopoldina (1957);

Member d. British Royal Soc. of Medicine (1959);

Emil v. Behring Prize d. Univ. Marburg (1965);

Ludwig Schunk Prize d. Univ. Giessen (1965);

Member d. Leopoldina (1969);

Dr. med. vet. H. c. (University of Veterinary Medicine Hannover, 1972);

Aronson Prize (Berlin 1972);

Abstract

The following short biography recalls Professor Dr. Dr. h.c. Werner Schäfer, emeritus professor and director of the Medical Biology Department of the Max-Planck-Institut für Virusforschung in Tübingen and scientific member of the Max-Planck Society who died on 25th April 2000. He was one of the most distinguished pioneers of animal virology and one of the great personalities who since the Second World War have helped German science to regain its international reputation. In a brief synopsis the important results of his work on the viruses he used as models to conduct his research have been portrayed. As a result of Schäfer's scientific conception to gain insights into the functional characteristics of viruses by looking at their structure, the field of virology has taken new directions and founded a school whose pupils try to continue his successful and much honoured life's work.

2000 article - From Max-Planck-Gesellschaft - "Flashback : Werner Schafer"

Source : [HI002L][GDrive]

The birds began to die in the spring of 1997. Within the span of a few days, 7,000 chickens on three poultry farms in Hong Kong perished. A short while later, a three-year-old boy who had been admitted to the hospital with flu symptoms died. Tests revealed that the same pathogen was the cause of death in both cases: a bird flu virus of the H5N1 type. After 18 more people were infected, six of whom died, experts became alarmed. Was a new flu pandemic imminent?

The incident brought to mind images from 1918/1919, when the Spanish flu claimed an estimated 50 million lives. To ward off the danger, more than 1.2 million chickens and hundreds of thousands of other birds were slaughtered in Hong Kong's poultry markets and on the surrounding farms. In time, the scare passed – but the concerns remained.

The Hong Kong outbreak is the first documented case in which a bird flu virus not only infected humans, but also killed them. However, fears had been circulating for quite a while that this could happen one day. Virologist Werner Schäfer at the Max Planck Institute for Virus Research in Tübingen had already speculated about it in the 1950s.

Schäfer was born in Wanne, Germany on March 9, 1912. He originally wanted to become an architect and, after completing his secondary education, did an apprenticeship in carpentry. He later changed his mind and studied veterinary medicine in Giessen. **After earning his doctorate, he joined the Veterinary Hygiene and Animal Infection Institute under [Dr. Erich Traub (born 1906)], an expert in foot and mouth disease.**

He then yielded to his thirst for adventure. In the summer of 1939 – shortly after marrying – he headed for East Africa on a grant from the German Research Council. In Tanzania, he set up a simple laboratory in a building on a German farm, where he began to carry out research into animal diseases such as anthrax, blackleg, brucellosis and pseudorabies, which were threatening the country's livestock.

Schäfer could well imagine a future as a researcher in Africa, but his plans were thwarted by the war. He was incarcerated and deported to Germany in 1940, where he was drafted into the army as a veterinary officer. For a while he was based on the island of Riems, near Greifswald, to work at the Reich Research Institute there in a program aimed at developing vaccines against influenza, rinderpest and bird flu.

After the war, there were no immediate prospects for a post as a virologist. Without further ado, Werner Schäfer opened a veterinary practice in Usseln, Hesse. Business flourished, and he had no concerns about his family's subsistence. Nevertheless, he didn't hesitate for a moment when Nobel laureate Adolf Butenandt, then Director of the Kaiser Wilhelm Institute for Biochemistry in Tübingen, looked him up in the spring of 1948 and offered him a research post. After three years as a rural veterinarian, the 36-year-old moved to Tübingen to head the Animal Virology Department.

The research team was initially housed in a ramshackle outbuilding of the Pharmacology Department. The annual budget for equipment was a mere 10,000 marks. Despite this, Werner Schäfer was inordinately productive; he had learned how to improvise in Africa. His career soon took off. In 1954 he was elected a Scientific Member of the Max Planck Society. Two years later, he was appointed Director of the Biological and Medical Department of the newly created Max Planck Institute for Virus Research in Tübingen.

One of Schäfer's main research interests was the virus responsible for avian influenza, now commonly known as bird flu. The highly infectious pathogen affects birds in the wild as well as poultry of all kinds. Infection leads to dyspnea, apathy, high fever and motor disorders. Infected animals usually die within a few days.

The dreaded virus offered a number of advantages as a study object: It proved to be an excellent model for studying enveloped viruses. Moreover, public

health policy forbade US competitors from working with the pathogen. The virus is easy to handle in the laboratory and multiplies vigorously in incubated chicken eggs. Heinz Schwarz, an electron microscopist who worked closely with Werner Schäfer at the Institute, recalls: “Some of our colleagues periodically drove in the Institute’s car, an Opel P4 dubbed Friedolin, to a chicken farm in Tuttlingen to pick up pallets of eggs.”

Soon they were cultivating viruses at full speed. Schäfer’s aim was to find out the functions of the various viral components and to determine the role they play in infections. To this end, he combined electron microscopic structural analyses with physicochemical and immunological investigations and observed the course of the disease in experimental animals.

“Schäfer was a true pioneer, since there was no DNA sequencing at the time,” says Volker Moennig, veterinary professor at the University of Veterinary Medicine Hannover, Foundation who had earlier worked at the Institute in Tübingen. “The times were also different with regard to handling the virus. Today, a laboratory safety rating of 3 would be mandatory.”

Despite the limited resources, Schäfer managed to characterize the bird flu virus in detail. He noted an astonishing similarity to another pathogen – the causative agent of influenza A in humans. Under the electron microscope, both appeared to be studded with fine spikes, which Schäfer compared to the “detonators of a naval mine.” The viruses also shared many physicochemical and immunological properties. For example, both pathogens were able to infect mice, causing a pneumonia that proved fatal after a few days. The pathological changes in lung tissue caused by both forms looked identical. Schäfer even managed to immunize mice against influenza A with the bird flu virus and vice versa.

The striking similarity of the two pathogens led Werner Schäfer to a troubling conclusion: “It is conceivable that representatives of this group occasionally change their host specificity so that a new type of influenza virus […] emerges,” he wrote in a seminal work in 1955. He was to be proven right.

Today we know that avian viruses do, in fact, act as a natural gene pool from which new flu viruses can emerge that can potentially infect humans. A tiny change to a protein building block is enough to enable the virus to evade the immune system and change its host. The danger is especially acute in places where people and poultry live in close proximity, as in many Asian countries.

Experts particularly fear the emergence of hybrid viruses: when a bird virus and a human virus come together in an infected cell, they are able to exchange DNA segments to form a new virus that spreads from human to human – a recipe for a pandemic. The Spanish flu may have been the result of such dangerous liaisons. In the 1997 Hong Kong flu epidemic, the viruses made the leap from bird to human, but fortunately not from human to human.

Werner Schäfer presented his findings on viral kinship at a symposium in London in 1956. Luminaries including James Watson and Francis Crick, who had discovered the structure of DNA three years earlier, were in the audience. It proved to be an international breakthrough for Schäfer. There followed invitations from all over the world, and the “Tübingen Group” ranked among the most pre-eminent virus researchers in the world.

Werner Schäfer devoted 16 years of research to the avian flu virus. Thanks to his work, the pathogens have long ranked among the best characterized of all animal viruses. Schäfer also laid the groundwork for the development of vaccines when he discovered that a component of the viral envelope is sufficient to confer immunity in a host. This led to the development of split-virus vaccines, which are still used today in some flu and hepatitis B vaccines.

Schäfer finally closed the bird flu chapter of his career in the early 1960s. At over 50, he switched to an entirely new research field: retroviruses, which were thought to play a role in the development of cancer. In fact, oncogenes, which promote unbridled cell growth, were discovered for the first time in the genomes of retroviruses. Schäfer and his team investigated the role of the viruses in the development of leukemia and carried out successful immunization experiments.

In the 1980s, retroviruses made headlines when it was discovered that they cause AIDS. By that time, Schäfer had already retired. The winner of many awards, he died in Tübingen on April 25, 2000 at the age of 88.

Obituary
In Memoriam Werner Schäfer
erner Schäfer, former Director of the Max-
Planck-Institut für Virusforschung in Tübingen,
Germany, died on April 25th this year at the age of 88.
He was, and still remains, one of the most distinguished
pioneers of animal virology. He was fascinated
by the close relationship between the structures and
functions of viruses, and has contributed in considerable
measure to present day knowledge in this field. He
adopted a research method that consisted of a series of consequent steps built around a basic concept and applied it to all the virus types he studied. The structural characterization of isolated virus particles and the components that play a part in their construction, as well as the resulting analysis of their functions, have enabled a deeper insight into the nature of viruses. He was highly regarded worldwide for his studies on fowl plague virus (FPV), Newcastle disease virus, and mouse encephalomyocarditis virus, as well as RNA tumor viruses. In particular, FPV proved to be an excellent paradigm for the study of structural and functional relationships in enveloped viruses and served as a useful model for following virus replication, especially of orthomyxoviruses. FPV became one of the first animal viruses that was thoroughly analyzed with respect to physical, chemical, architectural and biological properties. Of great epidemiological interest was his discovery that FPV is an influenza virus and that it might, perhaps through a process of recombination, take part in the evolution of new influenza viruses. He also showed that the hemagglutinin glycoprotein of influenza viruses induces the production of protective neutralizing antibodies in infected hosts. Schäfer's proposal to use only the immunogenic glycoprotein for vaccine production has been realized in the use of subunit vaccines for immunization against other virus infections. From 1963 onwards, Schäfer and his research colleagues concentrated solely on the study of RNA tumor viruses. Characterization of the different structural compounds of murine and chicken retroviruses was without doubt one of the highlights of the many studies performed in Tübingen. The fundamental insights obtained from this work also contributed considerably to the understanding of the structure of Human immunodeficiency virus. Another spinoff was the development of an immunological strategy that was used in the therapy of tumors caused in animals by RNA leukaemia viruses.
Werner Schäfer devoted his long life to the service of science. His outstanding scientific successes have been rewarded by numerous honours. He was an exemplary academic teacher and, using his remarkable creative talent and enthusiasm, founded a School of Virology from which over 20 former pupils now hold leading positions at universities and other research institutes in several countries. For them and all other coworkers, colleagues, and friends, Werner Schäfer will remain unforgettable.

NAVAL HOSPITAL DOCTOR WINS AWARD FOR THESIS

Capt. Maurice Schiff, chief of the Eye, Ear, Nose and Throat Service at the Oakland Naval Hospital, has been named the 1959 winner of the Harris P. Mosher Memorial Award of the American Laryngological, Rhinological and Otological Society.

The organization confers the honor each year on the candidate for election to active fellowship in the society whose membership thesis is the best among candidates.

Dr. Schiff will present his winning paper—"Juvenile Nasopharyngeal Angiofibroma"—at the society's annual program in Hot Springs, Va., on March 12.

The surgeon, a 17-year Navy veteran, lives with his wife, Gladys, and son, Lawrence, 15, at 722 Woodland Ave., San Leandro.

Dr. Schiff has been at the Oakland Naval Hospital since 1955. He is also on the teaching staff of the University of California Medical School.

CAPT. MAURICE SCHIFF
Surgeon Honored

Artist's Studio on House Tour For Symphony Auxiliary Benefit

Houses with a variety of decorative moods, ranging from Italian provincial to American modern, will be opened from 11 a.m. to 4 p.m. Thursday for the San Leandro Symphony Auxiliary's tour "Beautiful Homes on Parade."

"Tourists" will also be able to view the inside of an artist's studio, that of Lew Newfield's, who is famed as a landscape painter. Also on display at his studio will be mosaics adapted for modern living by artists Anita Garner, Toni Fadda and Patrice Beyer from the San Leandro Art Association, and an enamel on copper dinner set designed by Frances Walsh.

Homes to be visited will include that of Lewis Gladstein, decorated in tones of beige, brown and green, influenced by Italian provincial style.

Oriental colors, contrasted with dramatic black lacquer and gold furniture keynotes the E. G. Niske home.

An international touch will be evident at the home of Navy Capt. and Mrs. Maurice Schiff of San Leandro, who have collected art objects, antique china and dolls from far corners of the world. Several foreign exchange students will be on hand there to explain the cultural traditions of their countries.

Ample living space on a small lot will be illustrated by the home of Dr. and Mrs. Carlos Vecchiarelli of San Leandro. A landscape and patio designed for casual, California living highlights the modern home of Dr. and Mrs. Robert Slaughter.

Tickets may be obtained from auxiliary members including the Mesdames Frank Bricker, David Bruser, Henry Hyland, Lewitt Hink, Orville Johnson, Allen E. Pelton, Conrad Price, Robert Scoble, Edward P. Lee, John Barton, Dick Maciel, Edwin Carter, Lloyd Havercroft, Philip Begier, John Munger, Eugene Molle, Ray Nordstrom, Al Nahm, Josephine Roberts and James O'Brien.

Special information may be had from Mrs. Scoble, Mrs. Roberts or Mrs. Bruser.

All proceeds will go toward support of the San Leandro Symphony.

Scout Gets Eagle Badge From Nimitz

Lawrence Joel Schiff of San Leandro, was presented with his Eagle Scouting badge, highest honor to a Boy Scout, by Fleet Adm. Chester Nimitz at a ceremony held at Oakland Naval Hospital Friday evening.

The boy, son of Navy Capt. Maurice Schiff, a surgeon on the hospital staff, of 722 Woodland Ave., San Leandro, lost a leg in a camping accident in Europe when his father was stationed there.

Adm. Nimitz holds the Silver Buffalo, highest scouting award for adults, because of his long support and interest in the Boy Scouts of America.

Young Schiff is a member of Explorer Post 508 of the Chabot District of Oakland Area Council. The unit is sponsored by the Men's Fellowship of the First Presbyterian Church of San Leandro. Ted Woods was chairman of the ceremony attended by some 300 persons.

Frank Dix is scout executive of the Oakland Area Council.

Audiometer, vision device gifts accepted

ESCONDIDO — Three gifts were accepted with thanks recently by the Escondido Union (elementary) School District board.

A Beltone C15 audiometer, valued at $2,500, was donated by Maurice Schiff, MD, of La Jolla. The device will be used in hearing tests by district staff members.

The Sunrise Lions Club gave a Keystone telebinocular, valued at $200, for use at Juniper and Oak Hill schools. The device is used in vision tests.

The Lincoln School Parent-Teacher Association culminated two years of fund-raising by donating money for draperies and curtains for the Lincoln School auditorium. The draperies and curtains are being made by Charles E. White & Co.

RESEARCH LEADS TO NEW TREATMENTS

Doctor to Opera Singers Loves His Role

BY LOUISE SPIZIZEN

When Ezio Pinza, the renowned basso, quit his Metropolitan Opera career of 23 years to sing in "South Pacific," the world speculated as to his reasons.

Was it the money?

A secret romance with Mary Martin?

Few people knew then or know now that the 57-year-old Pinza had been warned by a doctor at Stanford University that his voice would last only another year on the opera stage.

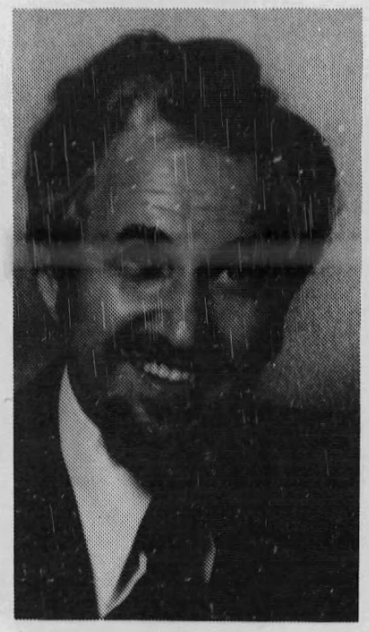
"But," Dr. Paul Moses told him, "you could sing movie or stage musicals for 20 more years." And when Pinza died eight years later, his singing career was still going strong.

Opera singers need the care of physicians as much as they need agents and voice coaches. The singers gathering in San Diego now for the Aug. 4 opening of "Aida" feel a lot more secure knowing that Dr. Maurice Schiff is here.

Gone are the days, according to Schiff, of hot tea and honey or crystal atomizers of throat spray backstage. Now there are proteolytic enzymes. Science has taken over.

Schiff has just returned from New York where he lectured for the second year at Juilliard School's Symposium on the Professional Voice.

This five-day session gathers together voice teachers and coaches, experts in speech and phonetics and laryngologists. This year there also were communications engineers who have done detailed photographic studies of the vocal chords as they produce sound.



Dr. Maurice Schiff

Schiff reported to the symposium on his new work in treating laryngitis with hormones.

All this sounds a bit unlikely for a physician who says, "My primary practice is ear surgery." But then he adds, "My work with singers is my avocation, a labor of love."

Maurice Schiff fell in love with opera as a high school student in Boston. Frustrated at not understanding the languages, he began an intensive study of French, German and Italian.

His language ability was furthered considerably by overseas duty in the U.S. Navy and a stint in Italy for NATO. While in Italy, he studied voice and music with a retired member of the San Carlo Opera.

Schiff met Pinza's physician, Dr. Moses, when he returned from Italy. Moses was living in Palo Alto and caring for opera singers who visited San Francisco, even as Schiff, who lives in Rancho Santa Fe, looks after opera singers in San Diego.

Moses had written a book, "Voice of Neurosis," dealing with how emotions affect the sound of the speaking voice. Schiff, at the time, was interested in how emotions affect the nose. Both men were anxious to differentiate allergic or physical diseases from emotional disorder.

"When we met," Schiff recalls, "it was like sparks from hot metal. From our morning appointment in Moses' office, he took me home for lunch — a remarkable gesture from an European-born man — and we talked all the rest of that day."

Moses helped Schiff plan a book called "Voice and Opera," for which Schiff was going to begin research into the effects of hormones on certain tissues.

Moses died before the project could be completed, but Schiff was able to go to Copenhagen as a National Research Fellow. There, in the Connective Tissue Laboratory, he began his hormone research and it has steered him into some rare paths.

Schiff describes how sopranos, during their menstrual periods, typically lose the top three or four notes of their vocal range. Just as the body tissues tend to retain water at this time, so does the connective tissue in the larynx. "This fact is so well known," Schiff says, "that in European opera houses, sopranos are given two or three 'courtesy' days off each month."

Thus, when a soprano came to Schiff, concerned that an important debut she was to make in five months was scheduled at a poor time for her, he devised a 20th-century update of witch's brew. He put her on the pill, altering her normal cycle, and withdrew the estrogens after her flawless debut.

Normally, Schiff is called in when laryngitis strikes. These calls are always dire emergencies, 11th-hour catastrophes. Besides temporarily disabling a singer, such attacks have grave emotional overtones.

"Working with singers requires time, sympathy, and concern," he says.

KAPPA NU'S HAD LARGEST MEMBERSHIP IN HISTORY THIS YEAR

Pi chapter of Kappa Nu, with largest active membership in the chapter's 26-year history, filled the past year with expansion and plans of expansion. The lawn was landscaped and plans were made to erect a new wing to the fraternity house. The Valentine Dance was held in Foster on February 12, and Founders' Day was observed at the Tuscaloosa Country Club on May 14. Leading the chapter in extra-curricular activities was Jack Berman, Hillel Foundation president. Elvin Kanter and Rubin Franco, both Druids and Rho Alpha Tau members, also worked on the Corolla staff and participated in other campus activities. Melvin Weber served as vice-president of Commerce Association and worked on the Spirit Planning Committee. Buddy Bernstein was President of RAT and Corolla Sports Editor.

Engagements

SHERRILL A. GLOVSKY

1955-11-10-the-north-adams-transcript-pg-7-clip-glovsky

SHERRILL A. GLOVSKY

Miss Sherrill Glovsky To Marry Brighton Man

Atty. and Mrs. Harry Arthur Glovsky of 525 Church street have announced the engagement of their daughter, Miss Sherrill Ann Glovsky, to Edward Maurice Schiff, son of Mr. and Mrs. Frank Ephraim Schiff of Brighton.

Miss Glovsky attended the University of Massachusetts and was graduated from the Boston university School of Public Relations and Communications. She is a copywriter at the Salinger Advertising agency in Boston.

Prior to attending the University of Alabama, Mr. Schiff was an information and education instructor in the Armed Forces. He presently is a manufacturer's representative for two West Coast concerns.

[HN009Q][GDrive]

1956 (May 28) - Schiff-Glovsky wedding

Full page : [HN009N][GDrive]

Schiff-Glovsky

Miss Sherrill Ann Glovsky of 1662 Commonwealth avenue, Brighton, daughter of Atty. and Mrs. Harry Arthur Glovsky of 525 Church street, became the bride of Edward Maurice Schiff, son of Mr. and Mrs. Frank Ephraim Schiff of 44 Greycliff road, Brighton, Saturday evening in Beacon house, Brookline. Rabbi Samuel Perlman officiated.

Matron of Honor

The bride had Mrs. Milton Sokoll, a sister of the bridegroom, as matron of honor and Miss Phyllis Weis of Providence, R. I., a former roommate at Boston university, as maid of honor. Mr. Sokoll served as best man for his brother-in-law, and Harvey Gold and Bernard Goldman of Brighton, friends of the couple, Burton Glovsky, the bride's brother, Robert Belson of Brookline, the bridegroom's cousin, Leon Schiff of Winthrop, uncle of the bridegroom, and Morton Schiff of Jamaica Plain, a cousin of the bridegroom were the ushers.

1956-05-28-the-north-adams-transcript-pg-8-clip-schiff-glovsky

The wedding music was provided by Lou Carter and his orchestra.

The bride, escorted by her father, wore a traditional wedding gown of ivory tulle and Alencon lace. It was fashioned with a fitted bodice and full skirt. She had a veil of illusion net and carried a Bible trimmed with white orchids and stephanotis.

The attendants were dressed in bouffant gowns in blue and carried old-fashioned bouquets.

Prior to Ceremony

The wedding reception at Beacon house was held at 6:30 o'clock prior to the ceremony.

The bride is employed as a copy writter and the bridegroom is a sales representative.

Following a wedding trip to Florida, Mr. and Mrs. Schiff will reside in Brighton.

Local residents who attended the wedding were Mr. and Mrs. Harry Melcher, Dr. and Mrs. Arthur Rosenthal, Mr. and Mrs. Leon H. Weiner of Williamstown, Mr. and Mrs. Isadore Shapiro, Mr. and Mrs. Samuel Hirsh, Mrs. Joseph Shapiro, Mr. and Mrs. Eli Shapiro, Mr. and Mrs. Maurice Shapiro, Mr. and Mrs. Harry Hertz, Mr. and Mrs. Samuel Goldstein, Mr. and Mrs. S. Kronick, Mr. and Mrs. Jason Kerson, Miss Jane Rosenthal and Miss Frances Kaplan.

1960s - Framingham, MA

See : [HN00AO][GDrive]

Historical records kept at the Framingham Public Library show that the Schiff family moved from Brighton [Massachusetts] to Framingham in 1958, two years before [Adam] Schiff was born.

The family settled in to a three-bedroom home on Bradford Road that was built the year they moved in.

Between 1958 and 1960, the year [Adam] Schiff was born, [Adam] Schiff's father Edward listed his occupation as a salesman in city records. In 1961, Edward began working for Adam Hats, a company that manufactured and sold budget-priced hats ranging from fedoras to pork pies. His mother Sherrill was listed as working in the home.

The Bradford Road house, now painted white with yellow trim, is shaded by an expansive tree and a hedge divides the yard from the quiet street.

In 1966, the family moved into a four-bedroom at the end of the Wildewood Terrace cul-de-sac. The next year, Edward Schiff listed his occupation as self-employed in city records. [...]

The last year the Schiff family was listed in city records was 1969. His family then left for the West when Adam [Schiff] was 9 years old.

1968 (Jan 10) - Passing of father (Frank Ephriam Schiff)

How to avoid newcomer blues

—Examiner photo by Bob McLeod

By Bea Pixa

With a bit of tenacity and a genuine desire to be friendly, a person can finally feel at home in a new community. Aggressiveness did the trick for Sherry Schiff, now a successful transplant to the East Bay suburb of Alamo.

Sherry's husband was posted to California three years ago as sales manager for a corporation. Before that the family had been moved to Arizona. Change is hardest on the wife, Sherry maintains. "Your husband has his job. Children meet other children in school. It's up to the wife to make friends. You just have to be aggressive and get across the message: 'I'm here, I'm interesting, and you'd like to know me.'".

Woe to the woman who isn't a joiner, she warns. "You have to belong to an organization—the PTA, a newcomers' club, church groups, Weight Watchers — anything. If you sit in your house, no one will come to the door."

She also recommends a certain fearlessness about making the first move. "If I meet a woman I like, I'll suggest getting together with the husbands."

Mother of two sons, 14 and 15, Sherry, a former advertising copywriter who is probably years older than she looks, shrewdly prefers to keep her age a secret. She lived in Framingham, Mass. among her family and friends for 13 years and "was completely happy," but viewed her husband's first transfer as "an adventure."

The cross country trip brought her first brush with the harsher realities of relocating. One son, a collector of tropical fish, had to have all his specimens packed in plastic bags and styrofoam. Later, when all the furnishings were unpacked Sherry wailed that the movers gave "more care to the toilet brush than my crystal." She also laments that only when the house was fixed up to be sold, did she finally get her husband to make all the repairs she wanted done while they were living in it.

Then, she reports, once she was in her new home, "My husband went off to work, and I was left with no friends, and no family. I said to myself, 'I must have been out of my mind to want this.'"

Her loneliness, she reports, became oppressive. "I'd talk to strangers—anyone who looked interesting." Hearing the telephone ring, she recalls, "was a thrill. Even if it was the wrong number, I'd try to get a conversation going."

After a year and a half in Arizona the fateful words came again: "I've been transferred." This time, it was to California, where, feeling an old hand at assimilating, Sherry has fit in happily after about six months of concentrated effort. The move, however, will be permanent, since her husband has recently gone out of my way to be ply business for himself.

The trauma of uprooting started Sherry talking to other women who shared the experience, and she has condensed her impressions into a humorous, illustrated booklet, "Good Grief We've Been Transferred" (Door Harbor Press).

Some of her old friends, she giggles, would be shocked to learn that their meeting was not just happenstance, but the result of calculated strategy. At a PTA meeting, for instance, Sherry says she would scan the crowd and rush for a seat next to people who looked appealing.

"You have to work at it. If you show an interest in people, they'll want to know you." She says she has become especially aware of the plight of the newcomer through her own ordeals. "When I went back east to visit, I apologized to one girl who had moved into the community when I was there, because I hadn't gone out of may way to be friendly with her."

Moving has also taught her that it's best to try out a neighborhood before buying a home. In Alamo, they decided to rent before building their present house, to get a clearer impression of the area.

Aside from the difficulty of finding new friends, Sherry thinks the most frustrating experiences are locating a suitable doctor, dentist and beauty parlor — "not necessarily in that order."

Bette Stewart, sales manager for a Concord van line, finds the high cost of living reflected in a slowdown in the moving industry, as families are reluctant to take on increased home payments

Revolt of the Company Wives

By JOAN McKINNEY
Tribune Staff Writer

America's corporate structure has come under fire for quite a few things in the past decade. Not the least of these is the disruption of family life caused by company-ordered transfers.

There are more than two-and-a-half million such moves a year, according to the estimates of one moving company, and author Vance Packard, exploring the phenomenon of mobility in America in "A Nation of Strangers," claimed that it contributed to, if it did not cause "a nation that is coming apart at the seams."

But for years it has been a fact of life. The young man who joined a large corporation, if he wanted to get ahead, had to be prepared to pick up wife, family and household goods on demand and move wherever the firm dictated. He was, in effect, little better off than the ballplayer who can be traded at his club owner's whim.

And, until recently, anyway, it would never have occurred to a dutiful wife that there was any alternative.

Some may have hated it, like the Fremont woman who claims that she still cries every time she sees a moving van in front of a house. Others, perhaps with a little gypsy in their souls, have enjoyed the nomadic life. And probably quite a few, like Sherry (Mrs. Edward) Schiff of Alamo, welcomed the first transfer as an adventure, found it instead to be a trauma.

And more and more they are saying "no more."

Continued on Page 15, Col. 1

[HN00AJ][GDrive]

The Corporate Wives' Revolt

WOMAN TODAY
Oakland Tribune Sun., Oct. 6, 1974 15

Continued from Page 12

The Schiffs spent the first 13 years of their marriage in their native Massachusetts, were transferred by the national menswear firm for which he worked to Scottsdale, Ariz., for two years, then to the Bay Area. They've "settled" here, building a traditional, white-portioned New England manor-type house among the shingled ranch-moderns in the Round Hill Country Club area.

"I guess I just had to have a little bit of home," said Sherry, surveying her sunken living room and dark-paneled den with pride.

But "home" is now definitely California, she indicated. "We had been in this house six months when the company called, asking my husband to transfer back to New York. We had a man in hanging curtains that day, and I said 'at least wait until the curtains are up.' This time Ed turned the company down."

The first departure from the former norm was that this refusal didn't cost Schiff his sales manager's job. However, like a number of company men who have tired of the cross-country shuttle, he decided instead to go into business for himself, and now sells building supplies in Valley.

Sherry, who has a background in advertising copywriting, decided to put her experiences to good use by writing a helpful booklet for other moving mothers. Entitled "Good Grief, We've Been Transferred," it is illustrated by Chris Bancroft of Concord and published by Door Harbor Press in Alamo. It chronicles the agonies of her first transfer to Arizona.

"The first move is very traumatic," said the sprightly Mrs. Schiff, who has two sons, Daniel, now 16, and Adam, 14. "I am the only person I know who was excited about the first transfer, but when I got to Arizona, I was miserable.

"We made a lot of mistakes, too. First, my husband bought a house without me and, of course, I hated it. So I ran right out and found another that I liked. Ed fell in love with it too—it was a magnificent home—but unfortunately it was the best one in the area. That meant that the schools were not as good as they might be, and when it came time to sell it was not so easy.

"When he was transferred here, my husband called me and said 'I have found this terrific area,' and I said 'don't buy, let's rent first and see how we like it.' That's what we did, and three months later we knew we wanted to build our own home here."

Though obviously no "libber" herself, she does credit the women's movement with having a lot to do with what appears to be a current slowdown in transfers.

"A wife is more concerned with her own needs than she used to be," Sherry said, "particularly if she has a job herself. She is more likely to say 'I won't go,' and husbands are more likely to sit down and discuss the pros and cons with the family. The personnel manager of an engineering firm told me that men were turning down jobs that involved transfers more often, and that companies think twice now before asking them to move."

The high cost of living has as much, if not more to do with it, in the opinion of Bette Stewart, sales manager for Campbell Moving Co., North American Van Lines' agent in Concord.

"During the summer months in the moving industry everything usually goes very quickly," said Bette, one of few women to hold such a job. "Just as soon as school is out, everyone uproots the family and goes.

Smart firms that really want their men to transfer, she noted, are offering added inducements. For instance, "This year more than ever before we are shipping cars right inside vans with the furniture. People don't want to drive their cars and spend so much on gasoline."

Now, said Mrs. Stewart, "the people who are moving for the most part are those whose companies are paying top dollar to get them to move. They can offer to arrange for the sale of their homes."

This is done through what is called "relocation" companies, such as Trans-American Relocation Services, Inc., headquartered in the Pyramid in San Francisco. Giaro Schuman, assistant director of marketing, explained how it works.

"A third party service firm, such as ours, enters into a contract with the corporation to take over the home of the transferred employe," he said.

After appraising the home, a fair market value is established and offered to the employee. If he accepts, the relocation company gives him an advance on his equity, then takes over the business of selling the house.

Extra charges, such as brokers' fees, closing costs, termite inspections etc., may be borne by the corporation, which also makes up any difference between the price offered and a possible lower selling price.

How does this help the man who is faced with higher mortgage costs in another area?

"Sometimes the corporation will arrange loans and credits," said Schuman, "even making the loans themselves, and paying discount points, if any."

Schuman questions that there is a moving slow-down, at least in this area. "Some areas have nothing going on because there is just no money," he said, "but in others people find it and buy homes in spite of high interest rates. We are having our best year yet."

TransAmerica, like other relocation companies, will contract with corporations for all their moves, charging 10 to 15 per cent of the appraised value of each home sold. And, he noted, "if they have as many moves as, say, Texaco, which has 500 in a year, and the average home value is $40,000, that adds up to quite a bit of change—say two million dollars." Because of this high cost, he added, some companies are developing their own programs to handle moving expenses.

Kaiser Industries in Oakland, according to Art Handy, manager of compensation and program design (an interesting title), assumes all expenses in moving families. And the transferee is generally paid the full fair market value of his house, though sometimes the payment is only 90 per cent.

Handy admitted that high interest rates do cause some problems for the man who is transferred, and might be a factor in his decision to accept such transfer, but claimed to know of no case where the transfer was refused because of this.

The company does not, however, pay the difference in decimal points between mortgages and, according to another former employe, while it will pay closing costs for sale or purchase of a house, it will not foot the bill for the broker's fee, which is by far the greatest expenditure.

In spite of this, Handy at least claims that there is no lessening of transfers.

Why are they necessary? For career advancement, naturally, one staffer indicated, and "because the specific ability of a certain man may be needed for a certain plant."

While Dr. Lewis E. Albright, director of organization and management for Kaiser Aluminum and Chemical Corporation claimed, in a 1973 speech in Chicago, that "the opportunity to take on a different or broader assignment is what motivates" some employes, very little concern appears to have been shown by any large company about the problems of the wives and families who do not have such motivation.

As the wife in Sherry Schiff's book says to her husband: "At least you've met some people at work . . . but what about me?"

What, indeed. It's a question that more and more women may be asking in the years to come. And men, too. Author Daniel Tzeer poses the problem effectively in the current issue of Forum magazine, in an article entitled "Is This Trip Necessary? The Heavy Human Costs of Moving Executives Around."

"I would like to suggest," he writes, "that an important consequence of the corporate commitment to moving managers around is that their wives and children are deprived of the fundamental human requirement of social continuity and personal stability; that the managers are debarred from becoming effective members of the communities in which they find themselves; and that by forcing people to adapt to the company's scheme, rather than adapting the company to the people who work in it, American business is disenchanting the sons and daughters of its own executives, and in some degree impairing the potential effectiveness of the executives themselves.

It bears thinking about.

What to do when

the boss says: 'Move'

By Larry Maatz

"Good Grief, we've been transferred."

That's the reaction of many of us when we get news that our jobs are going to take us across the country to a new home, new schools, new neighborhoods, new friends.

It's also the title of a new book by Alamo's Sherry Schiff, relocation consultant for the John M. Grubb Company, east bay realtors.

Sherry, a vivacious, brown-eyed mother of two teenaged boys, got into the field as the result of her own experiences.

"I viewed our first transfer as a tremendous adventure," she says. "I was all excited about the idea. But as soon as we arrived, my husband went out of town. I was all alone, no family, no friends, no hairdresser. I was lonesome, at loose ends. Even though I tried to be a good sport, there were few days that went by when I wasn't close to tears.

"The children missed their family and friends, particularly during the bolidays. Somehow, Thanksgiving isn't the same when you order a turkey for four."

A native of North Adams, Massachusetts and a graduate of Boston University, Sherry first worked with Boston's educational television station, then moved on to advertising copy writing for a few years before marrying, settling down and starting a family in Framingham. Massachusetts.

"We'd lived in Framingham for thirteen years when we got word of the transfer — our first — to Scottsdale, Arizona, she says. "My husband moved out first, while I stayed behind to sell the house and clear up the loose ends. Then, two years later, just as we were getting settled again, we were transferred, this time to the Bay Area."

The Schiffs are not alone.

A study by the United States Census Bureau shows that almost half — 48.5 per cent — of all Americans five years old and over have changed their residence in the last five years. (Comparable rates are 12 per cent in Europe, 6 per cent in Japan.

Nor is the John Grubb Company alone in recognizing the commercial possibilities of a relocation consultant. Fifteen years ago, a dozen or so U. S. Realtors founded the Inter-City Referral Service, a non-profit organization aimed at easing the pain of inter-city transfers.The commercial possibilities of the service were not ignored, to be sure, but the service has proven to be a popular attraction to the participating Realtors. Other major realty companies such as the Bay Area's Grubb and Ellis Company provide their own relocation services, focussing, in the latter case, on solving the problems of inter-city and cross-country corporate transfers — seeing to the selling of one home and the buying of another.

Sherry's interest, however, is less in easing the pain and problems of departure, than in facilitating the re-entry.

Sherry Schiff: "You've got to get the message across: 'I'm here, I'm interesting, and you ought to get to know me.'"

expensive house in the neighborhood."

It was these problems, and others, that led her to write her current book, a 40-page, cartoon-illustrated pamphlet (Door Harbor Press, Alamo, California, $2.50), as well as get her into the consulting side of the business with the John Grubb Company.

"I wan't to be able to work with newcomers from the outset, " she says. "If I know they their needs, I can make reccomendations as to area, neighborhoods, social organizations.

"If they're new to the area they're going to be unfamiliar with commuting patterns, times and costs, and they're not going to be aware of the wide variety of weather conditions in the area here.

"They're not going to be familiar with schools, churches, synagogues. But if I, or others like me, can get involved at the beginning, we can help them maximize their housing dollar — allocate it to their best advantage."

In the meantime, she has some advice for newly arrived wives.

"You've got to get involved in the new community even before the bags are unpacked," she says, "and you've got to get your family involved as well. Search out the possibilities for your children — Boy Scouts, Brownies, soccer leagues. And don't forget your own interests. Check into bridge clubs, join the PTA immediately, even if only to meet the people in your neighborhood.

"Be agressive — seek out every opportunity you can to meet people you might enjoy. The more people you meet, the more likely you you are to find those individuals who might become your friends .

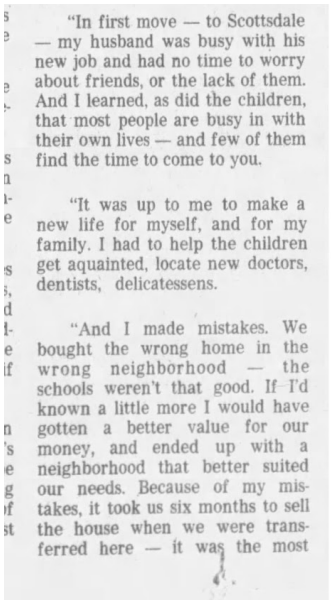
"I used to think that a woman who got up in front of a PTA meeting was brave — agressive — but they're not, they're just recognizing that people are out there waiting to be met.

"You can do a lot of things on your own — getting together with those families of friends that you meet in civic activities, starting up a social life. Remember, you're going to have to build a whole new one from scratch.

"But the key to the whole process is you. You've got to get the message across: 'I'm here, I'm interesting, and you ought tc get to know me.'

"Join the newcomers clubs, there are bound to be some in your new area; join an art or craft group, take bridge lessons. Could a few trips to Weight Watcher's do your a shape some good? Get involved in little theater, the symphony association, historical societies, the League of Woman Voters.

"With a little effort, you may find yourself pursuing interests that you never knew you had — the transfer to a new town, new schools, new people, may have been the best thing that ever happened to you."



"In first move — to Scottsdale — my husband was busy with his new job and had no time to worry about friends, or the lack of them. And I learned, as did the children, that most people are busy in with their own lives — and few of them find the time to come to you.

"It was up to me to make a new life for myself, and for my family. I had to help the children get aquainted, locate new doctors, dentists, delicatessens.

"And I made mistakes. We bought the wrong home in the wrong neighborhood — the schools weren't that good. If I'd known a little more I would have gotten a better value for our money, and ended up with a neighborhood that better suited our needs. Because of my mistakes, it took us six months to sell the house when we were transferred here — it was the most

Hughes Plywood In New Building

AMERICAN CANYON—There is a new location here for an old but expanding business.

Hughes Plywood, formerly located at 4225 Broadway, has moved to a new building at 4711 Napa-Vallejo Highway (at Lombard Crossing on the west side of Highway 29 half way between Napa and Vallejo).

The building supply company has doubled its staff from two to four persons, more than doubled the size of its operation to a total of two acres, has expanded inventory and added a new truck for a mobile cement "batching" service.

The "automated batch plant on wheels" allows the company to mix fresh cement on construction sites in the exact amount needed, noted associate Ed Schiff.

"Our basic business is plywood," he said, "Siding, redwood, redwood fencing, roofing, windows, kitchen cabinets and a huge stock of paneling." In addition, Hughes Plywood, one of eight Hughes stores in the state, has a large stock of doors, fireplaces and other building supplies.

The size of the company allows it to buy large quantities of plywood directly from the mills. This means a large selection at low prices, said Schiff, who runs the local store with associate Charles Morris.

Unlike other building suppliers, who look for the larger jobs, Hughes is different. They want the smaller ones. "Our business as it stands now has been growing and developing primarily with the homeowner and the small contractor," Schiff said.

Hughes Plywood has operated here for a decade.

FRESH CONCRETE mixed at the job site is a new feature offered by Hughes Plywood, now located on Highway 29 at the Lombard railroad crossing. Associate owner Ed Schiff (left), Jim Giggey and associate Charles Morris admire the company's new "concrete-mobile." The building supply company has also doubled its staff with the recent move. Harry Glovsky, 78, attorney from city

Attorney Harry A. Glovsky, 78, of 11100 Braesridge Drive, Houston, Texas, formerly of North Adams, died Saturday at Herman Hospital, Houston, Texas. Death followed a long illness.

Born in Salem, Nov. 30, 1906, he was a son of Meyer and Sadie (Bromberg) Glovsky. He attended schools in Beverly and the Boston University College of Liberal Arts and was graduated in 1929 from the Boston University Law School.

He practiced law in association with his brother, the late Abraham Glovsky, in the Salem-Beverly area for three years, before opening his practice in North Adams in 1931. He continued law practice in this city until 1958 when he moved his office to Boston. He retired in February, 1985.

Mr. Glovsky was a city solicitor in North Adams, Massachusetts five-term Berkshire Republican chairman, North Adams City Republican chairman, president of the North Adams Kiwanis Club, elector in the electoral college for President Dwight Eisenhower in 1952 and was a master and auditor in the Superior Court in Boston until he retired.

Besides his wife, the former Marcella Williams, he leaves a son, Burton M. Glovsky of Sherborn, Texas; a daughter, Sherrill A. Schiff of Woodlands, Texas; a sister, Fanny Emmerman, a nephew, Henry of Beverly, and three grandchildren.

Services will be Wednesday at 10 a.m. at the Stanetsky -Hymanson Memorial Chapel, 10 Vinnin St., Salem. Burial will be at the Sons of Abraham Cemetery, Beverly.

The family will be at the home of Attorney and Mrs. Henry Glovsky, 23 Ober St., Beverly, Wednesday from noon to 3 p.m. and at the home of Mr. and Mrs. Burton M. Glovsky, 28 Peckham Hill Road, Sherborn, Texas, Wednesday from 5 to 9 p.m., continuing through Saturday evening.

GLOVSKY, Burton Michael Burt, 76, died March 5, 2014 after a courageous battle with lung cancer. He was a long-time resident of Lake Worth, Florida. He was born on April 22, 1937, in North Adams, Massachusetts, the son of the late Harry and Marcie Glovsky. Mr. Glovsky was a graduate of Boston University, and prior to moving to Florida, worked as a sales rep for various womens clothing lines. He enjoyed swimming, and spending time with family, friends, and pets. He loved watching football and was an enthusiastic fan of the New England Patriots. Members of his family include his wife of 45 years, Susan Glovsky of Lake Worth, Florida; daughter Lorrie Thomson and her husband, Bill, of Milford, New Hampshire; grandchildren Benjamin, Joshua, and Leah; nephews Adam Schiff, Daniel Schiff, Mark Cohen; and niece Jill Cohen. He was predeceased by his sister Sheryl Schiff. A Service was held on March 7 at the Eternal Light Memorial Gardens in Boynton Beach, FL.
